Woodfibre LNG Project:

Waste Discharge Authorization Permit Application for Effluent (Stormwater / Drainage) to the BC Energy Regulator

November 2026

This package contains:

- **Environmental Protection Notice**
- **Forms and Maps**
  - **Final Application Form**
  - **Location Map**
  - **Site Map**
  - **Discharge Factors Form**
- **Technical Assessment Report**

ENVIRONMENTAL PROTECTION NOTICE

ENVIRONMENTAL PROTECTION NOTICE

Application for a Permit under the provisions of the *Environmental Management Act*

We, Woodfibre LNG General Partner Inc, as a General Partner on behalf of the Woodfibre LNG Limited Partnership, 900-1185 West Georgia Street, Vancouver, BC, V6E 4E6, intend to submit this application to the Director to authorize the discharge of effluent (stormwater / drainage) from the Woodfibre liquefied natural gas (LNG) facility.

The Woodfibre LNG facility is located approximately seven kilometres from Squamish, British Columbia within the traditional territory of Skwxwú7mesh Úxwumixw (Squamish Nation) and səlilwətaɬ (Tsleil-Waututh Nation). The site is situated at National Topographic System (NTS) A-001-K/092-G-11 on the following fee-simple lots: District Lot 6237 Group 1 New Westminster Dist., District Lot 5899 Group 1 New Westminster Dist., District Lot 2351 Group 1 New Westminster Dist., District Lot 2802 Group 1 New Westminster Dist., District Lot 8294 Group 1 New Westminster Dist., District Lot 8295 Group 1 New Westminster Dist., and District Lot 8296 Group 1 New Westminster Dist.

Separate contact water systems for contaminated, potentially contaminated, and non-contaminated water are used to manage stormwater runoff from the site according to contaminant risk. The source of effluent is stormwater runoff and drainage water that may have come into contact with industrial infrastructure, equipment, or operational areas during LNG facility commissioning and operations. Contaminated contact water that drains from equipment areas will be collected and conveyed to an Oily Water Treatment System (OWTS) for the treatment of extractable petroleum hydrocarbons (EPH) and total suspended solids (TSS) or transported off-site for appropriate disposal. The treated effluent from the OWTS will be discharged to Howe Sound at existing Outfall 10 (OUT-10) via the non-contaminated contact water drainage system. Treated effluent from the OWTS is expected to be discharged via OUT-10 during storm events, and occasionally during dry conditions (approximately once or twice per month). During these dry periods, the discharge rate will be limited by the OWTS treated water forwarding pump capacity of 30 m^3/hr (8.3 L/s). The characteristics of the effluent are provided in the table below.

Source	Parameter	Proposed Discharge Limit
Contact Water to OUT-10	Total Suspended Solids (TSS)	25 mg/L
	Extractable Petroleum Hydrocarbons (EPH) (C10-C32)	15 mg/L

Any person may review a printed copy of the application at the Squamish Public Library or download an electronic copy of the application material from the Woodfibre LNG website at https://woodfibrelng.ca/about-woodfibre-lng/regulatory-overview/regulatory-filings/.

Any person who may be adversely affected by the proposed discharge of effluent (stormwater drainage) and wishes to provide relevant information may, within 30 days after the last date of posting, publishing, service or display, send written comments to the applicant, with a copy to Environmental Stewardship, BC Energy Regulator at 6534 100th Ave, Fort St John, BC, V1J 8C5. Comments may also be submitted to by email to the applicant (info@wlng.ca), with a copy to the BC Energy Regulator (waste.management@bc-er.ca). The identity of any respondents and the contents of anything submitted in relation to this application will become part of the public record.

Dated this 28 day of October, 2026. Marnie Gohemas

Contact person: Janine Forrest

Email address: info@wlng.ca

Phone: 1-888-801-7929

Ministry of Environment and Climate Change Strategy

FINAL Application Form for a NEW Authorization

for authorization to discharge waste under the *Environmental Management Act*

New Permit, Approval, or Operational Certificate

FORM REFERENCE CODE: EPD-EMA-02.2

INSTRUCTIONS:

The application process is comprised of multiple steps that require the submission of a preliminary application and fee, followed by meetings with Ministry staff, and submission of a final application. **This form may be used for submission of a Final Application for a new Permit, Approval or Operational Certificate.**

Before completing this application form, please review the following:

- Waste Discharge Regulation under the *Environmental Management Act* at www.bclaws.ca; and,
- Ministry information and guidance documents that will assist in understanding the registration process and any other documents that may be required at http://www2.gov.bc.ca/gov/content?id=0876E90DA4744A449423D35EB4E09785.

It is preferred that this form is completed using a computer or typewriter. If completing this form by hand, please PRINT clearly.

Mandatory fields are marked with an asterisk (*). Please ensure all required fields are completed or the application form may not be accepted.

Once the Final Application has been submitted, the application will be screened for completeness before proceeding through the Screening Phase.

A Pre-Authorization Number and Tracking Number has been assigned to this request. Both numbers should be referenced on all documents submitted to support the new application request.

Under *Environmental Management Act, a* person is prohibited from introducing waste into the environment without authorization. Submitting an application to discharge is NOT an authorization to discharge.

This application can be submitted to the Ministry by email (preferred), mail or by courier.

Section 1: Application Information

***Tracking Number**	455731	1
***Pre-Authorization Number**	PE 113093	2
***Applicant Name**	Woodfibre LNG General Partner Inc., as General Partner on behalf of the Woodfibre L	3
***Facility Name**	Woodfibre LNG Export Facility	4
***Name of person completing this application**	Janine Forrest	5
***The person submitting this application is**	☒ The Applicant as named on the Preliminary Application Form, Section 2 ☐ The Agent, as named on the Preliminary Application Form, Section 4	6

The Application Package must include the following components or the application may be returned. Please refer to the guidance documents or contact the Ministry for further information on these requirements.

	Included	Not required / applicable	Submitted with Preliminary Application
Application Instruction Document (AID)	☐	☒	
Information Requirements Table (IRT)	☒	☐	☐
Technical Assessment Report	☒	☐	☐
Consultation Report	☒	☐	☐
Discharge Factors Application Form (Form EPD-EMA-03)	☒	☐	☐
Site Plan Form (Form EPD-EMA-09)	☒	☐	☐
Location Map Form (Form EPD-EMA-08)	☒	☐	☐

Section 2: Declaration and Signature

Please carefully read the following before placing your signature.

By completing this Application for an authorization, the Applicant understands and agrees with the following terms and conditions:

1. In this section:

   "Applicant" means the applicant as identified in section 2 of this application form;

   "Authorization" means the permit, approval, operational certificate, or amended permit, approval, operational certificate, sought pursuant to this application;

   "Director" means any statutory decision maker under EMA;

   "EMA" means the *Environmental Management Act*, S.B.C. 2003, c. 53, as amended or replaced from time to time;

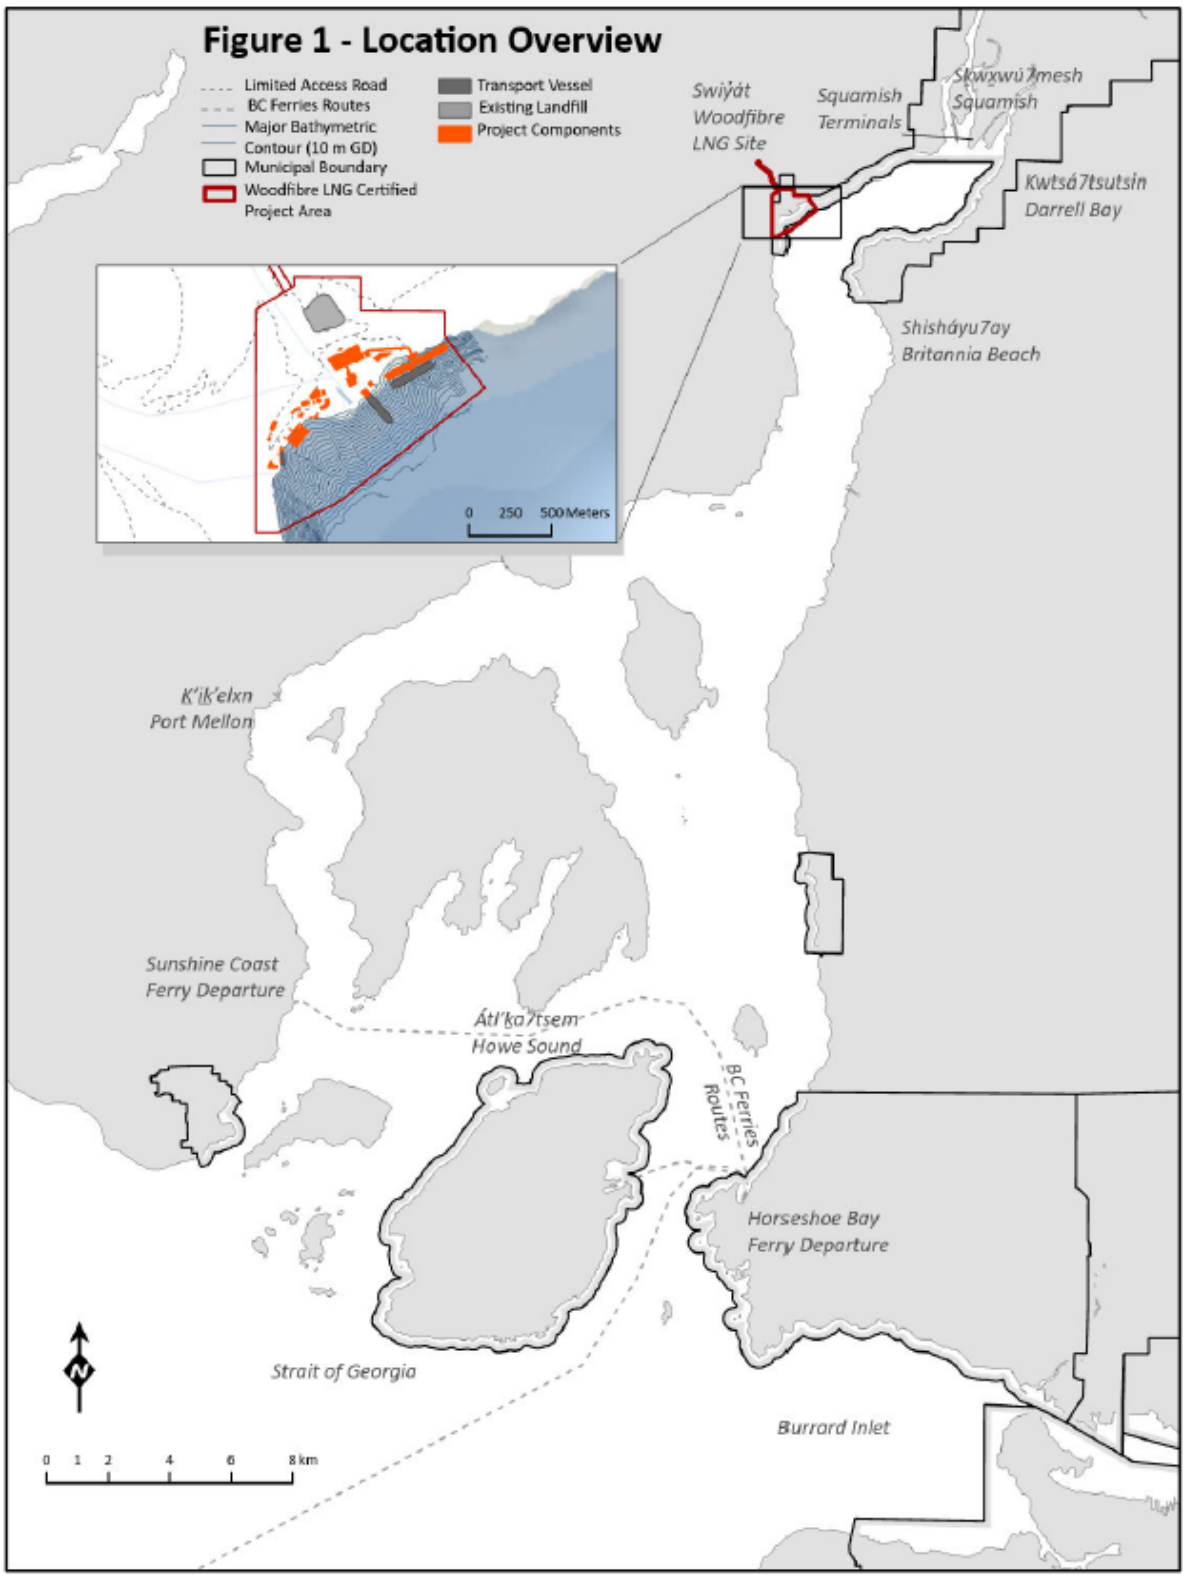
   "FOIPPA" means the Freedom of Information and Protection of Privacy Act, R.S.B.C. 1996, c. 165, as amended or replaced from time to time;

   "Province" means Her Majesty the Queen in Right of British Columbia;

   "Regulatory Document" means:

   a) this application form,
   b) any document that the Applicant submits or causes to be provided submitted to the Province or the Director in support of this application, and
   c) any document that the Applicant submitted or causes to be submitted to the Director or the Province pursuant to
      i. the Authorization;
      ii. any regulation made under EMA that regulates the facility described above or the discharge of waste from that facility; or
      iii. any order issued under EMA directed against the Applicant that is related to the facility described above or the discharge of waste from that facility.

2. In consideration of the Province receiving this application, subject to paragraph 3, the Applicant hereby irrevocably authorizes the Province to publish on the B.C government website the entirety of any Regulatory Document.



3. Despite paragraph 2, if the Applicant clearly identifies on the face of a Regulatory Document that the Regulatory Document, or clearly identified portions of it, are confidential and provides in writing with the document a rationale for why the document or portion thereof could not be disclosed under FOIPPA, the Applicant does not consent to the Province publishing the document or any portion of it if, in the opinion of the Director, the document or portion could not be disclosed under FOIPPA, if it were subject to a request under section 5 of FOIPPA.

4. In consideration of the Province receiving this application, the Applicant agrees that it will indemnify and save harmless the Province and the Province's employees and agents from any claim for infringement of copyright or other intellectual property rights that the Province or any of the Province's employees or agents may sustain, incur, suffer or be put to at any time that arise from the publication of a Regulatory Document.

5. The Applicant certifies that the information provided in this registration form is true, complete and accurate, and acknowledges that the submission of insufficient information may result in this registration being returned causing delays in the registration review process.

Discharge Factors Application Form

for authorization to discharge waste under the *Environmental Management Act*

New Permit, Approval, or Operational Certificate

FORM REFERENCE CODE: EPD-EMA-03.2

INSTRUCTIONS:

The application process is comprised of multiple steps that requires submission of a preliminary application and fee, followed by meetings with Ministry staff, and submission of a final application. **This form may be used in conjunction with the submission of an Application for a new Permit, Approval or Operational Certificate (Form EPD-EMA-02).**

Before completing this application form, please review the following:

- Waste Discharge Regulation under the *Environmental Management Act* at www.bclaws.ca; and,
- Ministry information and guidance documents that will assist in understanding the registration process and any other documents that may be required at http://www2.gov.bc.ca/gov/content?id=0876E90DA4744A449423D35EB4E09785.

It is preferred that this form is completed using a computer or typewriter. If completing this form by hand, please PRINT clearly.

Mandatory fields are marked with an asterisk (*). Please ensure all required fields are completed or the application form may not be accepted.

Once the final application has been submitted, the application will proceed through the Screening Phase to verify administrative and technical completeness.

A Pre-Authorization Number and Tracking Number has been assigned to this request. Both numbers should be referenced on all documents submitted to support the new application request.

Under *Environmental Management Act, a* person is prohibited from introducing waste into the environment without authorization. Submitting an application to discharge is NOT an authorization to discharge.

This application can be submitted to the Ministry by email (preferred), mail or by courier.

Section 1: Application Information

***Tracking Number**	455731	1
***Pre-Authorization Number**	PE 113093	2
***Applicant Name**	Woodfibre LNG General Partner Inc., as General Partner on behalf of the Woodfibre	3
***Facility Name**	Woodfibre LNG Facility	4
***Number of discharge points**	1	7

A copy of Section 2 must be completed for each discharge point. I.e. If there are three points of discharge, there should be three copies of Section 2 completed and submitted.

Section 2: Discharge Details

***Discharge Name** e.g. Planer Mill Cyclone #2	LNG Facility - Process Areas		1
***Discharge Type**	☐ Air ☒ Effluent ☐ Refuse		2
***Site ID as Referenced on Site Map**[1] e.g. Site A	OUT-10		3
Additional description (if needed)			4
Proposed treatment method and equipment to be used e.g. UV Disinfection, baghouse	Oily Water Treatment System (i.e., Corrugated Plate Interceptor (CPI) separator) [Note, comingled with stormwater at discharge point]		5
Discharge location description e.g. end of pipe, landfill, stack #1,etc	End of Pipe		6
***Discharge location position** i.e. end of pipe coordinates *must be in decimal degree format to 4 decimal places*	Latitude (e.g., 49.8952) N 49.6678 N	Longitude (e.g., 116.8177) W 123.2488 W	7
***Source of Data**	☐ GPS ☐ Survey ☐ Google Earth ☒ Other (specify): Project Plot Plan		8
If the Legal Land Description for the facility location is different than this discharge location			
Legal Land Description (Lot/Block/Plan) OR PID/PIN/Crown File No.	District Lot 2351, Group 1, New Westminster Dist; District Lot 8295, Group 1, New Westminster Dist; District Lot 8296, Group 1, New Westminster Dist;		9

[1] For each point of discharge, there must be a corresponding point displayed on a map using the Site Form (Form EPD-EMA-09.1).

*Table A: Proposed Flows

INSTRUCTIONS: Complete the maximum rate of discharge, and if applicable, the minimum, and/or average rate. Typically, only a maximum is needed. Include the duration of the discharge (e.g., hours/day) and the frequency of the discharge (e.g., days/week, days/month or days/year). Typically, a discharge may start when the authorization is issued and continues until the authorization is cancelled. If this discharge is to be time limited, this should be discussed at your pre-application meeting. All units are to be in System International (SI) metric units.

Rates are specific to the Oily Water Treatment System - there will be higher continuous flow rates during storm events

Minimum Discharge Rate+	Average Discharge Rate	Maximum Discharge Rate	Units (e.g. m^3/day)	Duration	Duration Units (e.g. hrs/day)	Frequency	Frequency units (days/weeks)
0		30	m3/hr	12	hrs	7	days

+ For composting facilities, maximum annual production capacity

*Table B: Proposed Contaminant Concentrations

INSTRUCTIONS: The contaminant data should be the characteristics of the waste when it enters the environment. Guidance on acceptable discharge quality may be found in applicable Provincial and Federal Regulations, Objectives, Guidelines, Criteria, Policies, Codes of Practice, Best Achievable Control Technology (BACT), Best Management Practices and, in some cases, draft documents.

Enter the contaminant and its maximum concentration and if applicable, the minimum, and/or average concentrations. All units are to be SI metric units. If the contaminant is to be discharged for a period less than the life of the authorization, enter the start and/or end dates. All air discharge rates are to be corrected to 20ºC, 1 atmosphere pressure, and zero water vapour.

Parameter or Contaminant Name[i]	Minimum Concentration	Average Concentration	Maximum Concentration	Units (e.g. mg/L)
Extractable Petroleum H	0		15	mg/L
Total Suspended Solids	0		25	mg/L

[i] For composting, type of material to be composted

Section 3: Receiving Environment Characteristics

Where a technical assessment of the discharge is not required by the Director, details of the receiving environment are to be listed here. If necessary, provide the information as an appendix to the application form. If a technical assessment is required, completion of this section is preferred, but optional. However, the details and supporting information to describe the receiving environment must be discussed in the technical assessment report.

Brief description of the receiving environment
e.g. name, description and characteristics of the water body, aquifer or airshed

Howe Sound near the mouth of Mill Creek, approximately 7km SW of Squamish, BC.
Further information is provided in the Technical Assessment Report.

Section 4: Distance to Nearest Specified Features

All measurements in metres

Water well	3000	m	**Serviced Lot**	7000	m	**Park or Protected Area**	6000	m
Reservoir	32000	m	**Recreational Area**	6000	m	**School or Daycare**	7000	m
Dwelling	5700	m	**Residential or Health Care Facility**	7000	m	**Surface water (lake, stream, marine)**	0	m

Revision 1

Preamble

Preamble

The Woodfibre LNG Project ('the Project') is a liquefied natural gas export facility located on the former Woodfibre Pulp and Paper Mill site in Nexwnéwu7ts Átlk̲´a7tsem (Howe Sound), approximately seven kilometers south of Sk̲wx̲wú7mesh (Squamish). The Project is on the historical location of a Sk̲wx̲wú7mesh Úxwumixw (Squamish Nation) village known as Swiy̓át. Swiy̓át and Nexwnéwu7ts Átlk̲´a7tsem (Howe Sound) are tied to the cultural well-being of Sk̲wx̲wú7mesh Úxwumixw (Squamish Nation) members, their ancestors, and their descendants, and to other Indigenous groups as defined in the Project's Environmental Assessment Certificates. Woodfibre LNG General Partner Inc. recognizes the importance of these areas to the Sk̲wx̲wú7mesh Stélmexw (Squamish People), and other Indigenous groups. Woodfibre LNG General Partner Inc. seeks to construct and operate the Project in a manner that is respectful of Indigenous values. This Technical Assessment Report for the Woodfibre LNG Facility is primarily written in English with some important place names, phrases, and passages provided in the Squamish language.

Temíxwiy̓ik̲w chet wa naantem chet ti temíxw Swiy̓át

Chet wa sméṅhemswit kwis ns7éyx̲nitas chet ti temíxw

We7ú chet kwis t'íchimwit iy íẇas chet ek̲' I tti.

Our ancient ancestors named this place Swiy̓át

We, as their descendants safeguard these lands

We will continue to swim and fish in these clear waters.

Executive Summary

Executive Summary

Woodfibre LNG General Partner Inc. (WLNG) is seeking a Waste Discharge Authorization (WDA) under the British Columbia (B.C.) *Environmental Management Act* for the discharge of treated stormwater and drainage effluent associated with commissioning and operation of the Woodfibre LNG facility ('the Project') near Squamish, B.C. This Technical Assessment Report (TAR), prepared by Lorax Environmental Services Ltd., provides the technical basis for regulatory review of the proposed discharge and demonstrates that the Project has incorporated appropriate water management, treatment, monitoring, and contingency measures to protect the receiving environment while supporting long-term facility operation. The TAR forms part of the WDA Effluent Permit application submitted to the B.C. Energy Regulator (BCER) and addresses the information requirements identified through the regulatory pre-application process.

The proposed authorization relates specifically to stormwater runoff and drainage water that may come into contact with industrial infrastructure, equipment, or operational areas during LNG facility commissioning and operations. Contact water that drains from equipment will be collected and conveyed to an Oily Water Treatment System (OWTS) for the treatment of extractable petroleum hydrocarbons (EPH) and total suspended solids (TSS). The treated effluent will be discharged to Atl'ka7tsem (Howe Sound) at existing Outfall 10 (OUT-10) via the non-contaminated contact water drainage system. Therefore, treated effluent will be mixed with non-contaminated contact water runoff prior to discharge to Howe Sound.

The scope of the TAR is limited to comingled stormwater runoff that has the potential to contact contamination sources during LNG facility commissioning and operations, and excludes discharges authorized under existing permits for treated landfill leachate and treated domestic wastewater, as well as effluent discharges associated with the FortisBC natural gas supply pipeline. The authorization is intended to support commencement of LNG facility operations following commissioning of the permanent water management systems and would remain in place throughout the operational life of the LNG facility.

The Project's water management program incorporates source control, runoff segregation, and treatment of potentially contaminated water. Stormwater is anticipated to represent the primary effluent stream managed during operations, with smaller contributions from operational activities such as vehicle washing. Water management infrastructure has been designed to collect, segregate, convey, treat, and discharge runoff in a manner that protects workers, safeguards Project infrastructure, and minimizes environmental risk. A key objective of the water management approach is to prevent contact between stormwater

runoff and potential contamination sources wherever practicable, thereby limiting the volume of water that requires active treatment and reducing overall management complexity.

To support these objectives, WLNG has developed an Operations Stormwater Drainage Management Program (SWDMP), which provides the operational framework for management of stormwater and drainage water throughout the life of the facility. The SWDMP describes the permanent drainage infrastructure, including diversion systems, collection systems, sumps, and outfalls, and establishes procedures for managing runoff based on its potential for contamination. The program also includes operational controls, monitoring requirements, residuals management, contingency planning, episode management for natural events, trigger-and-response protocols, and adaptive management measures intended to maintain compliance and support continuous improvement. Through implementation of the SWDMP, WLNG will systematically manage contaminated and potentially contaminated contact water, non-contaminated contact water, and non-contact water to minimize potential environmental effects associated with facility runoff.

The OWTS design has been informed by technical evaluations and is supported by a Best Achievable Technology Assessment (BATA). The OWTS utilizes proven industrial treatment methods, based on corrugated plate interceptor technology, to remove oil (*i.e.*, EPH) and suspended solids (*i.e.* TSS) through enhanced gravity separation. These separators are widely used in industrial wastewater treatment and are recognized as robust and reliable.

Commissioning of the water management system and the LNG Facility are expected to generate water streams that differ from routine operational runoff; therefore, additional controls have been incorporated into the commissioning strategy. Wastewater generated from activities such as flushing, cleaning, degreasing, hydrotesting additives, lube oil flushing, chemical cleaning, glycol systems, or other non-routine commissioning activities will be segregated from the permanent stormwater drainage system unless specifically assessed as suitable for treatment through the OWTS. Off-specification commissioning effluent will be collected and recycled or removed from site for disposal at an appropriate facility. Formal handover of the permanent water management systems from construction to operations will occur only after completion of mechanical completion, pre-commissioning activities, functional testing, cause-and-effect verification, instrument calibration, diversion logic testing, and commissioning acceptance testing in accordance with approved procedures.

To characterize the anticipated quantity and quality of discharge from OUT-10, the TAR includes an effluent model comprising both a water balance and water quality model. The

water balance was developed from the site hydraulic model to illustrate typical water management during the first 24 hours of a storm event, when some of the stormwater (*i.e.*, the first flush of 25 mm of rainfall) from the LNG Processing Area will be segregated and, if suitable, treated by the OWTS prior to discharge. Existing water quality monitoring data and OWTS treatment specifications were used to model water quality. The effluent model simulates the expected quantity and quality of contact water that will be discharged at OUT-10 during a 2-year return period 24-hour storm event, and during dry conditions when treated effluent from the OWTS may be the only source of water that is discharged at OUT-10. The effluent model included 113 parameters; predictions indicate that pH, TSS, EPH, total copper (T-Cu) and total zinc (T-Zn) may exceed the provincial long-term water quality guidelines (WQGs) for the protection of marine aquatic life in the effluent discharged to Howe Sound at OUT-10. The predicted T-Cu and T-Zn exceedances are attributed to particulate-bound metal fractions associated with TSS, which are considered less bioavailable than dissolved forms, while the predicted pH exceedances are attributed to natural background conditions rather than Project-related influences. The predicted concentrations T-Cu and T-Zn in OUT-10 effluent are within the range of concentrations that has been observed in Howe Sound receiving waters.

The mixing of OUT-10 effluent discharge with the Howe Sound receiving environment was modelled using a steady state mixing model, CORMIX. The CORMIX modelling software is recognized and accepted by professionals and regulators as appropriate for characterizing the initial dilution zone (IDZ) of receiving waterbodies. Discharge from OUT-10 is primarily associated with stormwater runoff or occasional OWTS operation during dry conditions; therefore, discharge from OUT-10 is expected to be frequent during rainy conditions and infrequent during dry conditions. Therefore, the model evaluates plume characteristics and effluent concentrations in Howe Sound for the two discharge scenarios: a storm event scenario representing discharge conditions for a 2-year return period 24-hour storm event, and a dry condition scenario representing discharge of OWTS effluent only. Wind is predicted to be a significant factor that influences effluent mixing. Therefore, the model was also configured to predict mixing for low, moderate and high wind speeds. The mixing model predicts that the OUT-10 initial mixing zone will form a buoyant effluent plume ranging from approximately 0.2 to 3.9 m in depth, with deeper mixing occurring with moderate and high winds.

Across the evaluated scenarios, concentrations of EPH, TSS, T-Cu, and T-Zn decline rapidly with distance from OUT-10, and all modelled parameters meet applicable concentration thresholds protective of chronic effects to marine aquatic life within approximately 80 m of the discharge. Based on the model results, the edge of the IDZ was established at a 100 m radius from OUT-10.

The environmental effects assessment considered parameters of concern (POCs) identified through the effluent model and focused on those parameters with the potential to exceed relevant WQGs or effect thresholds under modelled discharge conditions. The POCs originate from background conditions (*i.e.,* pH is naturally low in site runoff), TSS (*i.e.,* T-Cu and T-Zn are associated with TSS), and from the LNG Processing Area (*i.e.,* EPH from oils used in LNG processing equipment). The environmental effects assessment concludes that residual effects to marine aquatic life from the predicted WQG exceedances in effluent discharged from OUT-10 are unlikely to cause adverse effects to aquatic life in the receiving environment.

The monitoring and adaptive management framework has been developed to support regulatory compliance and verify environmental performance. Monitoring activities will include routine sampling and analysis of influent and effluent water quality, operational monitoring of treatment system performance, daily inspections of key treatment system components, and maintenance of operating records. Operational parameters such as flow, pressure, and turbidity will be routinely tracked to establish normal operating conditions and identify deviations that may indicate maintenance requirements or performance concerns. Monitoring information will be used to confirm compliance with discharge objectives, support operational decision-making, and inform adaptive management actions where necessary.

Overall, the Project will implement a comprehensive and integrated approach to stormwater and drainage management that combines source control measures, treatment, monitoring programs, and contingency planning. Effluent quality and quantity, and the IDZ have been modelled, and the environmental effects assessment indicates the modelled effluent quality discharged from OUT-10 is unlikely to cause adverse effects to aquatic life in the receiving environment. The predicted concentrations of T-Cu and T-Zn in effluent are within the range of concentrations observed in Howe Sound water, and are associated with less bioavailable, particulate-bound metal fractions associated with TSS. The predicted pH values reflect natural background conditions rather than Project-related influences. Therefore, discharge limits are proposed at OUT-10 for TSS and EPH, the parameters that are specifically treated by the OWTS. The proposed discharge limits are equal to the maximum EPH and TSS concentrations predicted by the effluent model and are based on the achievable OWTS treatment levels for these parameters.

1. Introduction

1 Introduction

This Technical Assessment Report (TAR) has been prepared on behalf of Woodfibre LNG General Partner Inc. (WLNG) by Lorax Environmental Services Ltd. (Lorax). WLNG is seeking a Waste Discharge Authorization (WDA) permit under the B.C. *Environmental Management Act*, Waste Discharge Regulation from the B.C. Energy Regulator (BCER) for discharge of stormwater / drainage effluent associated with the operating Woodfibre Liquified Natural Gas (LNG) export facility ('the Project') near Squamish, B.C. The effluent consists of stormwater runoff that may come into contact with potential contamination sources associated with LNG facility commissioning and operations. Contact water that drains from equipment and piping is collected and conveyed to an oily water treatment system (OWTS) for treatment. Treated water, along with local stormwater runoff, is discharged to Atl'ka7tsem (Howe Sound) through the existing outfall, Outfall 10 (OUT-10). This TAR addresses the information requirements that have been identified for review and approval of the WDA, and are listed in Appendix 1.1-1.

1.1 Project Overview

The Project is located approximately seven kilometers southwest of Skwxwú7mesh (Squamish), B.C. on the northwestern shoreline of Nexwnéwu7ts Átlk'a7tsem (Howe Sound) (refer to Figure 1-1). The Project site is within the Traditional Territory of the Skwxwú7mesh Úxwumixw (Squamish Nation) at the historical site of Swiẏát, a Skwxwú7mesh Úxwumixw (Squamish Nation) village.

The Project has capacity to liquefy up to 2.1 million tonnes per year of natural gas and an LNG storage capacity of 250,000 m^3. The stored LNG will be exported to market via LNG carriers. Refer to Section 2 for further description of the Project.

The site is comprised of fee simple, industrially zoned, brownfield lands, along with existing stakw (water) lots. The site previously operated as a pulp mill facility from 1912 until 2006. There is no road access to the Project site; all personnel, equipment, and supplies are brought in by vessel via Nexwnéwu7ts Átlk'a7tsem (Howe Sound).

1.2 Regulatory Context

The Project underwent a comprehensive environmental assessment process from 2013 to 2015, where WLNG received:

- An Environmental Assessment Certificate (EAC) for the Certified Project Area (CPA) from the Environmental Assessment Office (EAO) under the B.C. Environmental Assessment Act (EAC #E15-02) in 2015;
- An environmental assessment approval from Skwxwú7mesh Úxwumixw (Squamish Nation) through the Squamish Nation Environmental Assessment Agreement (SNEAA) in 2015; and
- A positive Federal Decision Statement (FDS) from the Canadian Environmental Assessment Agency (now known as the Impact Assessment Agency of Canada (IAAC) under the Canadian Environmental Assessment Act, 2012 in 2016.

There have been subsequent amendments issued by EAO, Skwxwú7mesh Úxwumixw (Squamish Nation) and IAAC. The provincial, Sḵwx̱wú7mesh Úxwumixw (Squamish Nation), and federal environmental assessment processes have each yielded conditions of approval that Woodfibre LNG must address, which include effluent discharges.

The BCER issued the Facility Permit AD#100105360 in July 2019, and there have been subsequent amendments issued.

There are currently three permits for the discharge of effluent from the Project site to Howe Sound:

- Permit 1239 for the treatment and discharge of leachate to Howe Sound from the closed on-site landfill that supported previous activities on the site. This permit was issued in 1975 and has been transferred to WLNG as it will be applicable during operations. The discharge is to Howe Sound is via an existing submerged outfall east of Mill Creek, separate to the stormwater/drainage system outlets.
- Permit 2334 for treatment and discharge of domestic wastewater to Howe Sound from the sewage treatment plants that supported previous activities on the site. This permit was issued in 1975 and has been transferred to WLNG as it will be applicable to the WLNG sewage treatment system during operations. The discharge is to Howe Sound is via an existing submerged outfall south of Mill Creek, separate to the stormwater/drainage system outlets.
- WDA Permit 111578 for treatment and discharge of construction contact water to Howe Sound from the Project construction area via two discharge locations: SP-W-OUT and SP-E-OUT. This permit was issued in 2024 and will not be

required after the Project completes the transition from the construction stormwater management system to operations stormwater management system (refer to Section 2.2 for further information).

There are two Certificates of Compliance (CofC) on the site due to the historical land use, as follows:

- Site Identification Number 9930 and 17544 were issued in December 2014 for the upland portion of the site and marine sediments within the existing water lots, respectively. Each certificate specifies a number of controls that are required to be maintained. These conditions will be maintained during facility operations.

1.3 Objectives of the TAR

This TAR forms part of the WDA permit application and is intended to provide a summary of technical information required by BCER to assess the application. The required information is identified in the Information Requirements Table (IRT) that WLNG submitted to the BCER on March 21, 2025, and in the pre-application package submitted to the BCER on March 18, 2026. The Table of Concordance that shows where the requirements of the IRT are addressed in the TAR is included as Appendix 1.1-1.

The specific objectives of this TAR are to:

- Describe the Project, including an overview of the relevant Project phases/activities for context;
- Summarize the environmental setting of the Project related to the proposed stormwater/drainage effluent discharge;
- Describe the approach for site water management and treatment;
- Characterize anticipated discharge associated with the operation of the LNG facility to the receiving environment, including the location, duration, estimated volume and quality of treated effluent discharged at Outfall 10 (OUT-10);
- Characterize the potential environmental effects of the stormwater/drainage effluent discharges; and
- Identify mitigation measures, the monitoring program, as well as contingency measures that will be implemented to manage potential environmental risk.

1.4 Scope of the TAR

The scope of this TAR is limited to the discharge of the comingled stormwater runoff that has the potential interface with contamination sources during LNG facility commissioning and operations activities.

1.4.1 Temporal Scope

WLNG is seeking the WDA permit by Q2 2027, when the permanent water management systems are forecast to be commissioned and put into service to manage the stormwater runoff and drainage during commissioning and operations.

The WDA would remain in effect until the permanent water management systems are closed/decommissioned at the end of the LNG facility life and/or effluent discharge ceases to Howe Sound, which could be after year 2067 based on the 40-year LNG export license issued by the Canada Energy Regulator.

1.4.2 Spatial Scope

The spatial scope of this TAR is defined by where stormwater will come into contact with the Project during commissioning and operations activities. For the purposes of the WDA permit application, the Project site is defined by the CPA authorized under the EAC which includes the following fee simple lots:

- Parcel Identifier 015-791-611, District Lot 6237, New Westminster District
- Parcel Identifier 015-822-061, District Lot 5899, New Westminster District
- Parcel Identifier 015-910-717, District Lot 2351, New Westminster District
- Parcel Identifier 031-813-992, District Lot 2802, New Westminster District

The CPA also includes two lots along the foreshore (District Lot 8294 and 8295) and one marine lot (District Lot 8296).

1.4.3 Exclusions

The scope of this TAR excludes the following effluent discharges; however, they are referenced in the cumulative effects discussion in Section 5.5:

- Discharge of effluents authorized by Permit 1239 (treated landfill leachate) and Permit 2334 (treated domestic wastewater).
- Effluent discharges that may be associated with pipeline operation that supplies natural gas to the WLNG facility (operated by FortisBC).

1.5 Structure of the TAR

This TAR is structured as follows:

- Section 2 contains the description of the various Project activities. This is intended to provide context for the LNG facility operations, including the nature of contact water that is expected to be generated.
- Section 3 contains the description of the environmental setting. This section is intended to provide information on the terrestrial, freshwater aquatic and marine environment of the Project and the receiving environment for effluent discharges.
- Section 4 summarizes the management plans relevant to the operation of the stormwater drainage and treatment systems, and contains the description of the effluent discharges. This includes consideration of the water management system and water treatment, and summarizes the results of the hydraulic, effluent quality and mixing models prepared to provide quantitative predictions of discharge volumes and quality.
- Section 5 contains a discussion on the potential effects of the predicted discharges to aquatic life.
- Section 6 discusses the proposed monitoring plan and discharge limits that are requested for the WDA permit.

2. Project Description

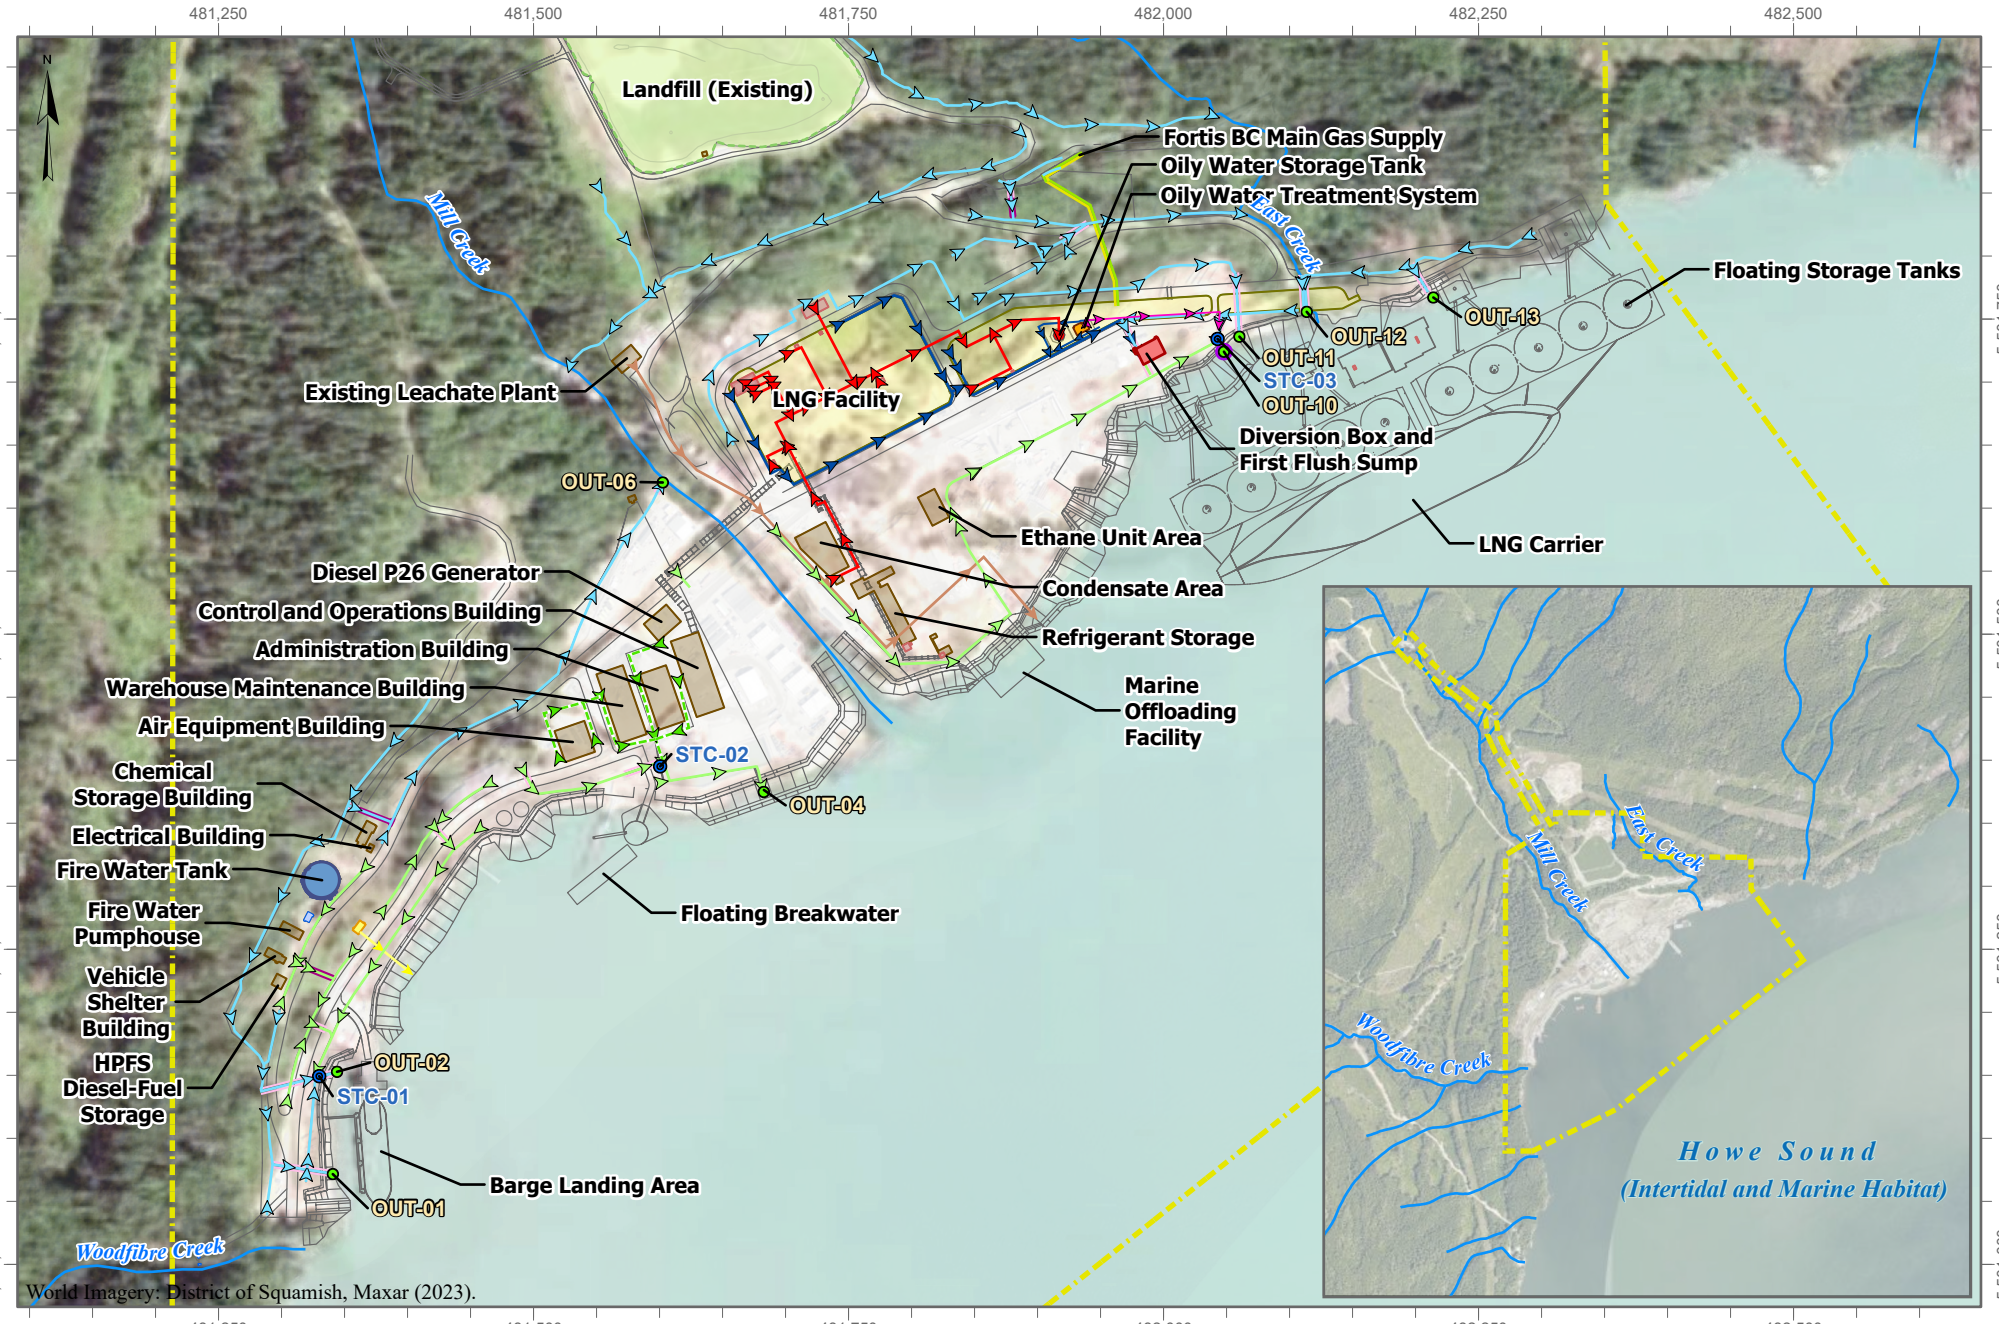
2 Project Description

This section provides a description of Project operations (Section 2.1), followed by an overview of the activities that occur during commissioning (Section 2.2) and closure / post-closure (Section 2.3). Figure 2-1 illustrates some of the key components of the Project, including the discharge locations. Further detailed information on the stormwater drainage system design and outfalls into Howe Sounds are provided in Section 4.

2.1 Operational Description

Natural gas will be supplied to the LNG facility by FortisBC from western Canadian market hubs. In the land-based LNG facility processing area, located on the east side of Mill Creek, the impurities and other components of the incoming pipeline quality gas that would not meet the LNG specification are removed. Condensates (lighter hydrocarbons) are also removed from the gas and stored as a liquid for export to market. The natural gas is then cooled (liquefied) to -162°C to produce LNG, using a propane pre-cooled mixed refrigerant (C3MR) technology. The LNG is subsequently transferred to the marine terminal via the LNG jumper arms for storage in floating storage tanks (FSTs), which are two retrofitted Moss LNG vessels (FST-1 and FST-2). The LNG is then loaded into an LNG carrier for export to market via loading arms located on FST-2.

There are a range of utilities that support the LNG process, which include:



- Electrical power sourced from B.C. Hydro; there are substations and transformers on site that support the distribution of power to the various LNG facility equipment.
- Boil-off gas (BOG), which is the vapor that is generated off the LNG when it is subject to warmer temperatures. It is recovered from the FSTs and LNG loading system, recompressed in BOG compressors, and routed to the fuel gas system that supplies fuel gas to several systems in the process. Surplus compressed BOG is reinjected back into the LNG liquefication process.
- Process heat, which is supplied by a gas-fired Heating Medium Heater (*i.e.*, furnace) to a closed loop of heating medium fluid.
- Tempered water, which is an inhibited ethylene glycol solution. It is used to cool several compressors and circulated back to the air-cooler in a closed loop system.

For the purpose of further describing facilities and associated discharges, the site is conceptually divided into four main zones (refer to Figure 2-2):

- LNG Processing Area;

- Refrigerant and Condensate Storage Area;
- Marine Terminal Area; and
- Industrial Area (on the west side of Mill Creek).

The Project area contains a mixture of site surface coverings, including paving (asphalt or concrete) for the operational process areas, containment areas, buildings, and primary access roads that connect the various areas of the Project site; and granular base for non-operational areas near the Refrigerant and Condensate Storage Area.

PROJECT #: A825-1

FIGURE: 2-2

2.1.1 LNG Processing Area Overview

The LNG Processing Area is comprised of several modules that contain the required equipment and piping to process LNG. These modules are often referred to when describing elements of the stormwater drainage system, as several of the modules have their own dedicated drainage sump related to the OWTS. For ease of reference in the TAR, the module number, purpose and relevance to the stormwater drainage system is outlined in Table 2-1, with further information provided in Section 4. Note the LNG jumper arms located on module M05 connect the LNG Processing Area to the Marine Terminal Area.

2.1.2 Refrigerant and Condensate Storage Area Overview

The refrigerants, including propane and ethane, used in the liquification process are stored south of the LNG Processing Area. There is a dedicated unloading area as the refrigerants are imported to site. The condensate is stored in a tank south of the LNG Processing Area. There is a dedicated condensate loading area (via truck or barges) to support the export from site.

2.1.3 Marine Terminal Area Overview

The FSTs and LNG carrier loading area is located at the Marine Terminal on the foreshore of Howe Sound. LNG Transfer Platform Modules M05A and M05B (Figure 2-2) will be used to transfer the LNG from the LNG rundown lines using jumper arms into the FSTs. The FSTs are two retrofitted Moss LNG vessels (FST-1 and FST-2) that are permanently moored at the Marine Terminal Area, with each vessel containing five LNG Storage Tanks. The LNG carrier, with the assistance of tugs, moors parallel to the FSTs; LNG is then loaded onto the LNG carrier for export.

2.1.4 Industrial Area Overview

Supporting infrastructure is located in the Industrial Area on the west side of Mill Creek, which includes the following:

- Permanent buildings, including the Warehouse and Maintenance Building, Administration Building, Control and Operations Buildings, Instrument Air Building, Vehicle Shelter Building and Chemical Storage Building;
- Utilities, including chlorinated fire water/service water, potable water, sanitary wastewater, diesel fuel (to support essential diesel generators and the diesel fire water pumps), nitrogen, and instrumentation air;
- Personnel transportation infrastructure, including the passenger ferry and guard house; and
- Material handling ramps such as roll-on/roll-off (RoRo) and west ramp.

Table 2-1:
Summary of LNG Processing Area Modules

Module No.	Module Name	Purpose[1]	Relevance to Stormwater/Drainage System[2]
M01	Pre-treatment Module	Removes impurities from the natural gas feedstock.	Carbon dioxide (CO_2), hydrogen sulphide and other sulphur compounds and volatile organic compounds are removed from the feed gas using an amine solvent. These impurities are then separated from the solvent stream in the solvent regenerator, and the impurities are incinerated in the thermal oxidizer in M09. The amine solvent is used within a closed drainage system so any excess solvent will gravity drain to a solvent drain drum for reuse in the process. However, there is a curbed area and sump dedicated to the collection of stormwater in this area in the event stormwater came into contact with amine. This module includes gaseous and liquid hydrocarbon containing equipment and piping; therefore, the stormwater collected near those systems is classified as contaminated contact water and directed to the OWTS.
M02	Liquefaction Module	Removes the condensate (butane, pentane, *etc*.) and cools (liquefies) the treated gas using C3MR system.	This module includes gaseous and liquid hydrocarbon containing equipment and piping; therefore, the stormwater collected near those systems is classified as contaminated contact water and directed to the OWTS.
M04	Boil-Off Gas (BOG) Compressor Module	BOG compressor helps with the capture of natural gas that re-vapourizes (boils off) and its re-injection back into the process to be reliquefied into LNG or for use as fuel gas.	This module includes gaseous and liquid hydrocarbon containing equipment and piping; therefore, the stormwater collected near this system is classified as contaminated contact water and directed to the OWTS.
M09	Process Utility Module	Supplies the critical common process utilities for the LNG process, including the tempered water system, hot oil (heating medium) heating system and the thermal oxidizer.	The heating medium equipment is within a closed drainage system, so any excess heating medium will gravity drain to a heating medium drain drum for reuse in the process. However, there is a curbed area and sump dedicated to the collection of stormwater in this area in the event stormwater came into contact with heating medium. The tempered water system is also a closed loop system that is within curbed areas to contain any inhibited ethylene glycol spills or leaks. The thermal oxidizer incinerates impurities removed from the feed gas in M01 (separated from the amine solvent stream).
M10/M11	Powerhouse Modules	Supplies and distributes the critical power for the LNG process.	There are a range of transformers on site used to change the voltage based on the system requirements, including dry and wet types. Wet transformers contain a dielectric oil to insulate and cool the transformer, therefore are located within curbed areas to contain any spills and leaks.
M13	Flare Knock Out (KO) Drums Module	Flare KO drums are designed to protect the facility's flare system by separating any liquids from gases set to be flared, ensuring safe and efficient flare operation.	This module includes hydrocarbon containing equipment and piping; therefore, the stormwater collected near those systems is classified as contaminated contact water and directed to the OWTS.

Notes:
[1] The purpose provided herein is high-level only and not intended to be a detailed description of all the processes/activities that occur within each module.
[2] Refer to Section 4 for further information related to the stormwater drainage system.

2.2 Commissioning Activities

The permanent stormwater management systems are planned to be commissioned and put into service ahead of the overall LNG facility commencing operations, and prior to the completion of construction activities. WLNG has retained McDermott International Ltd. ("McDermott") to lead the construction, pre-commissioning and commissioning activities, with supports from various subcontractors and WLNG oversight/assurance. There is a robust handover process implemented between McDermott and WLNG prior to each system being formally handed over to WLNG to start-up and operate. Temporary infrastructure used solely to support construction activities is forecast to commence being systematically decommissioned in the second half of 2027, once no longer required for site water management, including the backfilling of the sedimentation ponds and demobilization of the construction wastewater treatment plants. The transition from the temporary (construction) to the permanent (operations) stormwater management system is further described in Section 4.1.10.

The temporary construction stormwater management system includes sedimentation ponds, construction wastewater treatment plants, and associated temporary works, as authorized under WDA Effluent Permit PE-111578. There are two authorized discharge locations into Howe Sound (SP-W-OUT and SP-E-OUT) under WDA Permit PE-111578.

The temporary construction stormwater system will be used while the permanent stormwater management system is being constructed, pre-commissioned, commissioned, and handed over (from McDermott to WLNG) as part of substantial completion. The intent is that the permanent stormwater management systems within each module/area will have completed commissioning activities prior to the LNG equipment and piping in that area being commissioned, and prior to the commissioning of the OWTS. Formal handover of the permanent water management systems from construction to operations shall occur only after completion of:

- mechanical completion;
- pre-commissioning activities;
- functional testing;
- cause and effect verification;
- instrument calibration;
- diversion logic testing; and
- commissioning acceptance testing in accordance with approved procedures.

During LNG facility commissioning, any wastewater generated from flushing, cleaning, degreasing, hydrotesting additives, lube oil flushing, chemical cleaning, glycol systems, or other non-routine commissioning activities will be segregated from the permanent stormwater drainage system unless specifically assessed as suitable for treatment through the OWTS. Off-specification commissioning effluent shall be collected and recycled, or removed from site for disposal at an appropriate facility.

2.3 Closure & Post-Closure

The *Energy Resource Activities Act, LNG Facility Regulation*, Section 2.1 defines the activities required to be undertaken when an LNG facility permit holder no longer intends to operate the LNG facility. WLNG will also develop a decommissioning plan in accordance with the EAC and FDS.

Prior to the cessation of operations, a review will be undertaken to identify whether subsequent industrial activity could re-use any of the LNG equipment or supporting works, and what components need to be retained beyond closure for environmental purposes (*e.g.*, treatment facilities) or future industrial activities (*e.g.*, ancillary buildings). The review will also identify what equipment and materials can be salvaged for reuse or recycling, or require offsite disposal at a licensed facility.

Closure activities will include de-energizing / de-pressurizing and draining of systems, and residuals will be removed for proper management and disposal. Discharges to the environment will be undertaken in conformance with the WDA in effect. Generated waste will be classified and subsequently disposed of in accordance with the applicable Acts and Regulations.

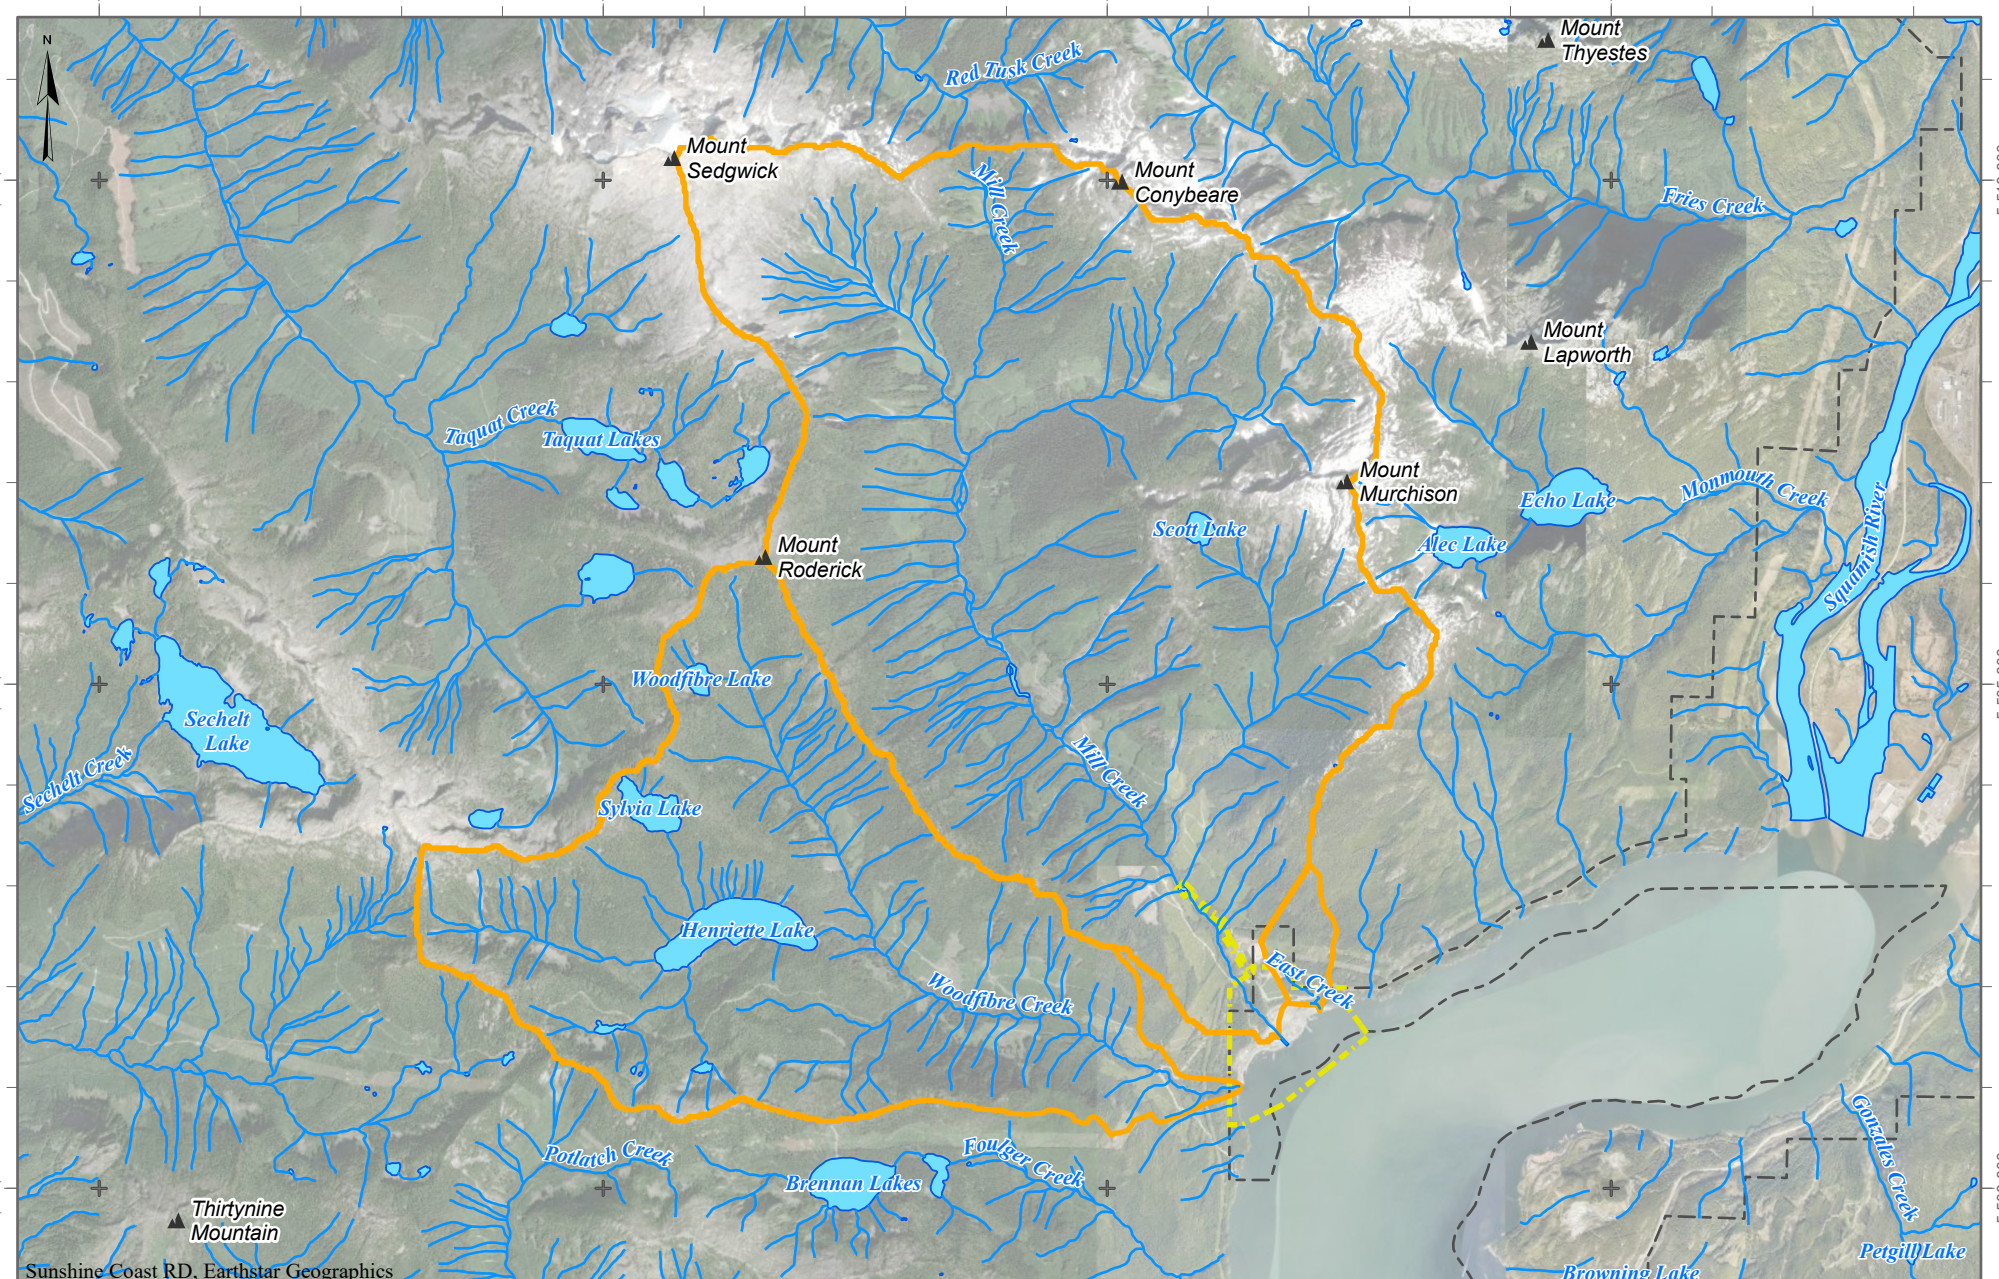
Post-closure activities will be developed once it is determined what infrastructure will remain on site, and if the outcomes of the contamination testing program result in further actions in consultation with the BCER. Waste generated during post-closure activities will also be classified and subsequently disposed of in accordance with the applicable Acts and Regulations.

3. Environmental Setting

3 Environmental Setting

This section describes the environmental setting for the WLNG Project. It provides contextual information and describes current conditions for the terrestrial landscape, watercourses, and marine environment. The information provided includes a description of physiography, bedrock and soils; groundwater, surface water quantity and quality; as well as oceanography, marine sediments, marine water quality and marine ecology. Due to the lead time required for TAR preparation, the construction records and environmental monitoring records presented in this section extend to the end of May 2025 (water quality data) and August 2025 (sediment quality and excavations), when the data analysis for these sections commenced.

3.1 Physiography



The Project is located on the northern basin of Howe Sound, a coastal fjord located in the Strait of Georgia. The inlet extends 42 km south from the mouth of the Squamish River to the base of the inlet, which is near West Vancouver (Figure 1-1). In the vicinity of the Project site, steep mountains descend from the Tantalus Range peaks of roughly 2,000 m elevation to the shore of Howe Sound. The area was inundated by the Cordilleran Ice Sheet during the Fraser Glaciation. The slopes above the Project property comprise steep bedrock cliffs and forested terrain. The mid-slopes are generally bedrock controlled, sometimes with a veneer of colluvium and occasionally with a veneer of glacial till. A fluvial fan forms a small level area at the edge of Howe Sound where the Project site is located.

The hillsides and mountain valleys located at higher elevations above the Project property are generally undeveloped and mainly forested. However, there are gravel roads that extend up the valleys from the Project site, and in the past clearcut logging has been undertaken in the watersheds that extend inland from the Project site. In recent years, logging related road construction has been conducted approximately 1 km south and east of the Project property and extending into the lower extent of the Woodfibre Creek watershed. Transmission line right of ways cross the hillslopes and watersheds above the Project site and some ground preparation activities have been undertaken within the right of ways on the north side of the Mill Creek watershed approximately 200 m northwest of the Project property. Ground preparation for a natural gas compressor station has also been initiated at the north side of the property and within the East Creek watershed area.

Three small streams discharge to Howe Sound within the Project boundaries as shown in Figure 3-1. The largest of these is Mill Creek which flows from Mount Sedgewick through moderately steep terrain and a small canyon prior to bisecting the fluvial fan at the edge of

Howe Sound. The creek is tidally influenced through most of flat area formed by the fluvial fan. The smaller Woodfibre Creek drains Woodfibre Lake to the north-west and Henriette Lake to the west, and the south-facing slopes of Mount Roderick through a steeply descending slope at the southern edge of the Project site. East Creek has smallest watershed of the three creeks with the lower extent of the stream with lower tributaries flowing through constructed channels, and ultimately discharging through a culvert on the eastern side of the Project site.

The Squamish River discharges from a large glacier-fed watershed to the head of the Howe Sound approximately 5 km east of the Project. The river is the dominant freshwater input to Howe Sound and exerts a significant influence on the Howe Sound marine water quality within the marine portion of the Project site.

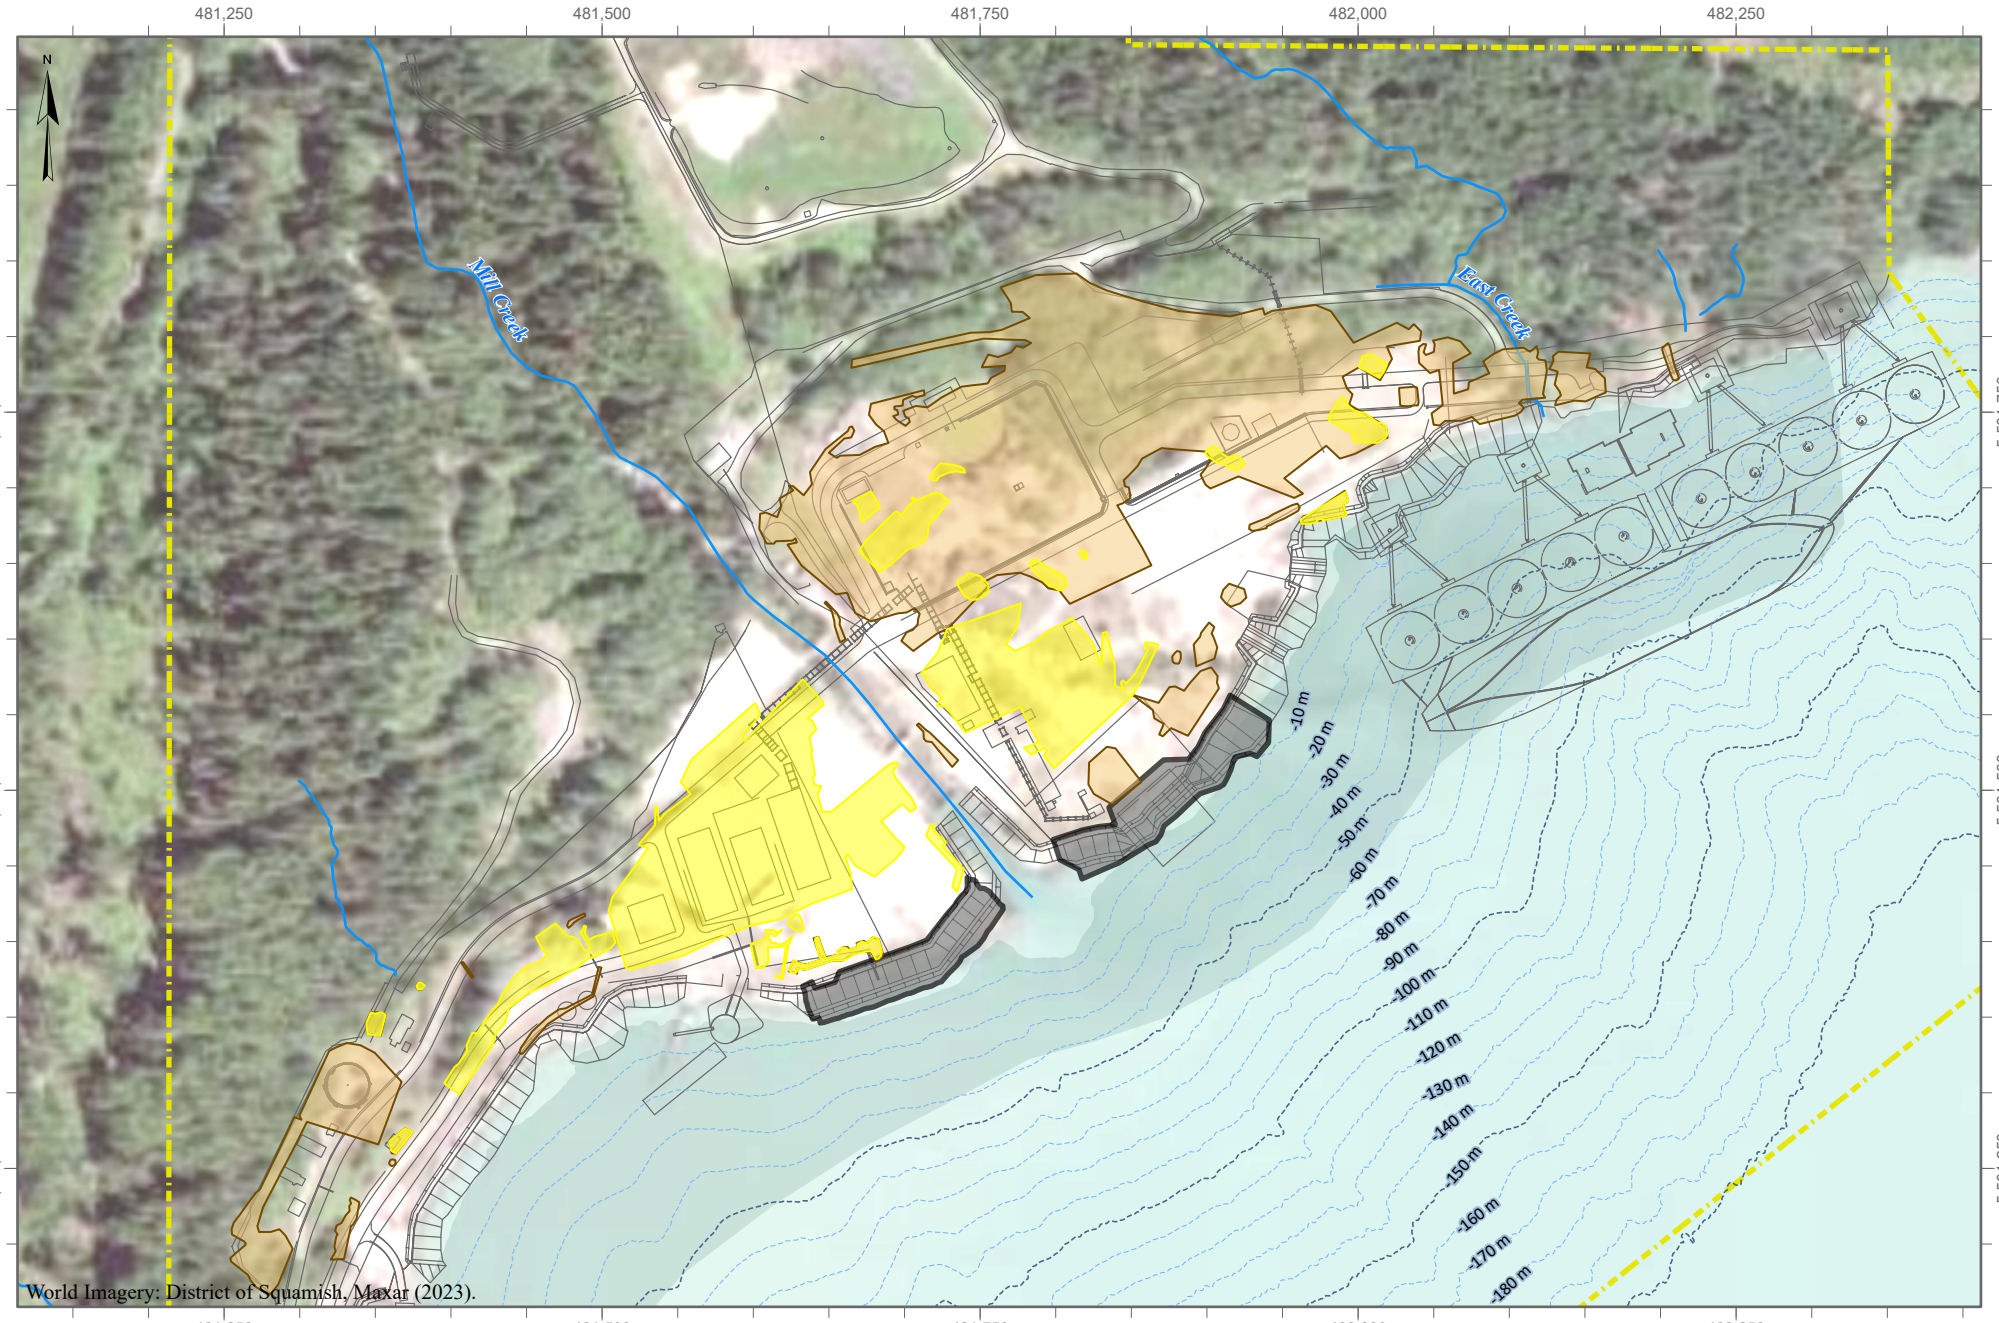
3.2 Soils

Soils within the Project site are predominantly composed of glaciofluvial or glaciolacustrine sediments (overburden) deposited in an alluvial fan by Woodfibre and Mill Creeks. These have been altered by excavation and deposition of fill material undertaken from the time the Woodfibre Pulp Mill was constructed and operated beginning in the early 1910s until the mill closed in 2006. Site investigations conducted under the B.C. *Environmental Management Act* Contaminated Sites Regulation (CSR) in 2005 identified potential contaminant sources which may have impacted soil and marine sediment quality at the Project site, including placement of fill, fuel tanks, chemical storage tanks, an asbestos storage area, wood chip storage and handling, and pulp processing areas (Keystone 2014a). Site remediation was completed in 2014.

Additional rounds of soil characterization were conducted in 2020 and 2021. Site preparation activities occurred from June 2022 to October 2023. The construction contractor mobilized to site in September 2023, with construction of the facility commencing in November 2023. As of August 2025, most of the Project site was covered with imported fill material that is discussed in Section 3.3. This section summarises the soil monitoring conducted from 2006 to August 2025.

3.2.1 Monitoring Prior to Site Preparation (2006 to 2021)

Soil monitoring was conducted from 2006 to 2014 to delineate contamination in areas of potential concern identified by the preliminary site investigation (Keystone, 2014a). These investigations identified localized soil contamination in historic fill locations where metals, light extractable hydrocarbons (LEPH), and heavy extractable hydrocarbon (HEPH), were present at concentrations greater than the CSR soil matrix standards for Industrial Land (IL) for the following applicable pathways: human intake of contaminated soil, toxicity to soil invertebrates and plants and groundwater flow to surface water used by aquatic life (freshwater and marine). Remediation of the upland area of the Project site was completed, and a CofC was issued in December 2014 for the uplands portion of the Project site by the B.C. Ministry of Environment (refer to Section 1.2).



Further soil monitoring was carried out from December 2020 to February 2021 for the evaluation of soil quality specifically within the planned Project excavation areas (Keystone, 2021a). The monitoring included a surficial soil investigation and an investigative drilling program that were supplemental to the monitoring conducted 2006 to 2014 (Keystone 2014a). The monitoring objectives were to classify soil quality based on CSR definitions within the general excavation areas, to delineate contaminated soils within and adjacent to the Project construction areas, and to estimate the volumes of soil that would require different management approaches based on the soil classification. The soil

quality results were screened against the CSR IL standards for the following site-specific factors: human intake of contaminated soil, toxicity to soil invertebrates and plants, and groundwater flow to surface water used by aquatic life (freshwater and marine). Metals (arsenic [As], cadmium [Cd], cobalt [Co], chromium [Cr], copper [Cu], iron [Fe], manganese [Mn], nickel [Ni], lead [Pb] and zinc [Zn]) were present at greater than the CSR IL standards. The results of this monitoring program were presented in the Technical Assessment Report for the Woodfibre LNG Export Facility Construction Phase Waste Discharge Authorization (Lorax, 2023) that supported the application for WDA Effluent Permit PE-111578.

3.2.2 Site Preparation Demolition and Soil Improvement (2022 to 2023)

Pre-construction site preparation occurred from June 2022 to October 2023 and included demolition of all existing buildings and structures within the Project footprint, removal of building foundations, as well as stripping and grubbing of vegetation. Demolition materials included lumber, metal, asbestos and concrete. The lumber, metal and asbestos were shipped off site to facilities that were licensed to receive them for disposal or recycling. Stripped vegetation was disposed of in the on-site landfill prior to its closure in 2023. Concrete was crushed and re-used as fill on-site to maintain a minimum one metre thick cover over contaminated materials, in compliance with the CofC for the upland portion of the site.

The demolition and soil improvement areas disturbed by site preparation activities are shown in Figure 3-2. The activities were overseen by a registered professional for contaminated sites (Keystone Environmental Ltd.). To facilitate excavation of concrete foundations it was necessary to excavate some soils below the one metre cap adjacent to the foundations. Soils excavated from within areas of environmental concern and soils with invasive plant species were stockpiled on site for further characterization and disposal during construction. Approximately 35,000 m^3 of soils were stockpiled for further characterization (refer to Section 3.2.3).

3.2.3 Construction Overburden Excavations and Monitoring (2023 to 2025)

Excavations were managed in accordance with the requirements of CofC 26250-20/9930 for the uplands portion of the Project site, and were overseen by the registered professional for excavation works (Stantec Consulting Limited). Approximately 297,000 m^3 of soil and overburden were excavated from upland areas within the Project site from November 2023 to August 2025. Materials that either did not meet the CSR IL standard, contained invasive plant species, or were otherwise not suitable for construction use were disposed off-site at facilities licensed to receive these materials. A total of 152,000 m^3 were exported from the site as of August 2025, with the balance used as fill. Excavations of soil and overburden were collectively tracked as overburden. The excavation areas are shown in Figure 3-2.

Excavations from upland areas were placed in on-land stockpiles with sub-samples tested for chloride, metals, volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), volatile petroleum hydrocarbons (VPH), LEPH and HEPH (Keystone, 2024b and 2026). Soil stockpiled during pre-construction soil improvement excavations was also tested (refer to Section 3.2.2). A total of 97 samples were collected. All test results met the CSR IL standards, except soluble chloride and metals (As, Cu, Cr, selenium [Se] and Zn) in one or more samples. The test results are summarized in Table 3-1 and are tabulated in Table 1 of Appendix 3.2-1.

Out of the 97 upland soil samples, 10 were duplicate samples. Overall, the quality control evaluation of duplicate sample pairs indicated that the soil samples have acceptable representativeness (Appendix 3.2-1, Table 2). However, elevated variability was observed for metals (Cd, mercury [Hg], Pb and antimony [Sb]) and PAHs in one or more duplicate data pairs, and was attributed to heterogeneous distribution of these parameters in the soils.

Table 3-1:
Upland Soil Quality Summary (2024-2025)

Parameter	CSR IL Standard (mg/kg) [1]	Concentration Range (mg/kg)
Leach Test Parameters		
Chloride, soluble	600	399 - 407
pH, Soluble (2:1)	-	6.29 – 10.20
Volatile Organic Compounds (VOC), Halogenated		
Carbon Tetrachloride	50	<0.020 - <0.020
Chlorobenzene	10	<0.020 - <0.020
Chloroform	50	<0.020 - <0.020
Dichloromethane	50	<0.080 - <0.080
Tetrachloroethene	2.5	<0.010 - <0.010
Trichloroethene	0.3	<0.0090 - <0.0090
Volatile Organic Compounds (VOC), Non-Halogenated		
Benzene	2.5	<0.0050 - 0.011
Ethylbenzene	200	<0.010 - 0.02
Styrene	50	<0.030 - 0.26
Toluene	0.5	<0.050 - <0.050
Xylenes, Total	20	<0.040 - 0.15
Polycyclic Aromatic Hydrocarbons (PAH)		
Benz(a)anthracene	10	<0.020 - 3.4
Benzo(b+j)fluoranthene	10	<0.020 - 4
Benzo(k)fluoranthene	10	<0.020 - 1.4
Dibenz(a-h)anthracene	10	<0.020 - 0.6
Indeno(1,2,3-cd)pyrene	10	<0.020 - 2
Naphthalene	75	<0.010 - 14
Phenanthrene	50	<0.010 - 18
Pyrene	100	<0.020 - 10
Strong Acid Extractable Metals		
Antimony (Sb)	40	0.13 - 22.7
Arsenic (As)	10	2.54 - **18.4**
Barium (Ba)	1,500	57 - 531
Beryllium (Be)	1 – 500 [2]	<0.20 - 0.71
Cadmium (Cd)	1 – 50 [2]	<0.050 - 1.1
Chromium (Cr)	60	11.2 - **139**
Cobalt (Co)	25	4.62 - 8.66
Copper (Cu)	150 – 1,500 [2]	14.9 – **2,300**
Lead (Pb)	1,500 – 15,000 [2]	2.69 – 1,070
Molybdenum (Mo)	650	1.26 - 6.64
Nickel (Ni)	70 – 500 [2]	5.04 - 55
Selenium (Se)	1	<0.50 - **2.65**
Silver (Ag)	40	<0.050 - 0.344
Thallium (Tl)	25	<0.050 - 0.14
Tin (Sn)	300	0.22 - 55.2
Uranium (U)	150	0.831 - 18.8
Zinc (Zn)	150 – 200 [2]	29.3 - **555**
Petroleum Hydrocarbons		
LEPH (C10-19)	2,000	<100 – 1,400
HEPH (C19-32)	5,000	<100 – 1,200

Notes:
Values highlighted in **bold** font exceed the corresponding CSR IL standard.
[1] The most stringent applicable CSR (Schedule 3.1) numerical soil standard for Industrial Land (IL) use for human health protection (intake of contaminated soil), and environmental protection (toxicity to soil invertebrates and plants, groundwater flow to surface water used by aquatic life). The hexavalent Cr standard is applied to the total Cr results.

3.2.4 Construction Foreshore Excavations and Monitoring (2024)

Construction activities included the installation of foreshore armouring to protect the site from erosion caused by wave action along the Howe Sound shoreline, and for installation of the Marine Offloading Facility (MOF). Excavation of pre-existing foreshore fill was required to facilitate this work and was conducted in 2024. The locations of the foreshore excavation areas are shown in Figure 3-2. All foreshore excavated materials were removed from the Project site by barge for off-site disposal. A total of 39 samples was collected from excavated material that was stockpiled in the barges and were tested for chloride, metals, PAHs, LEPH and HEPH. Information and monitoring results for the foreshore fill excavations were provided by McDermott and Roe Environmental Inc.

The results are screened against the CSR IL standards. The test results are summarized in Table 3-2 and are tabulated in Table 1 of Appendix 3.2-2. The IL standard is exceeded in one or more samples for chloride, metals (As and Sb) and PAH (phenanthrene). The elevated As and Sb concentrations detected in a few samples may be from historical use of anti-fouling agents that contained compounds made from these elements. Creosote covered pilings and boards from historical wharf structures are the likely source of PAHs in samples that were collected in the vicinity of these structures.

Out of 39 foreshore samples, 10 are duplicate samples. The quality control results are tabulated in Table 2 of Appendix 3.2-2 and indicate that, overall, the soil results have acceptable representativeness for metals. Elevated variability was observed for PAHs in a majority of the duplicate pairs, and was attributed to heterogeneous distribution of these parameters in the foreshore materials.

Table 3-2:
Foreshore Fill Quality Summary (2024)

Parameter	CSR IL Standard (mg/kg) [1]	Concentration Range (mg/kg)
Leach Test Parameters		
Chloride, soluble	600	220 – **2,910**
pH, Soluble (2:1)	-	6.99 – 9.61
Polycyclic Aromatic Hydrocarbons (PAH)		
Benz(a)anthracene	10	0.094 - 9.17
Benzo(b+j)fluoranthene	10	0.074 - 4.3
Benzo(k)fluoranthene	10	0.03 - 1.5
Dibenz(a-h)anthracene	10	0.0059 - 0.215
Indeno(1,2,3-cd)pyrene	10	0.018 - 0.7
Naphthalene	75	0.031 - 5.88
Phenanthrene	50	0.588 - **58.7**
Pyrene	100	0.391 - 29.7
Strong Acid Extractable Metals		
Antimony (Sb)	40	0.19 - **311**
Arsenic (As)	10	1.89 - **10.9**
Barium (Ba)	1500	37.6 - 1310
Beryllium (Be)	1 - 500 [2]	<0.10 - 0.96
Cadmium (Cd)	1 - 50 [2]	0.046 - 0.513
Chromium (Cr)	60	8.35 - 37.9
Cobalt (Co)	25	3.24 - 14.8
Copper (Cu)	150 - 1,500 [2]	11.6 - 677
Lead (Pb)	1,500 - 15,000 [2]	5.79 – 1,900
Molybdenum (Mo)	650	1.02 - 10.4
Nickel (Ni)	70 - 500 [2]	3.76 - 200
Selenium (Se)	1	<0.20 - 0.62
Silver (Ag)	40	<0.10 - 0.5
Thallium (Tl)	25	<0.050 - 0.109
Tin (Sn)	300	<2.0 - 144
Uranium (U)	150	0.636 - 4.38
Zinc (Zn)	150 - 200 [2]	23.7 - 101
Petroleum Hydrocarbons		
HEPH (C19-32)	5,000	<200 - 410
LEPH (C10-19)	2,000	<200 - 240

Notes:

3.3 Overburden and Bedrock Geology

3.3.1 Geologic Setting

The Coast Plutonic Intrusive Group dominates over 70 percent of the Howe Sound region by area and includes the Mill Creek watershed south of Mount Sedgewick, based on publicly available regional mapping. The Jurassic to Tertiary-aged Coast Plutonic Group is composed of plutonic rocks such as quartz diorite, granodiorite, granite, and minor gabbro.

The local formation is mapped but is unnamed based on available bedrock mapping (Cui *et al.,* 2017). The unit consists of mid-Cretaceous granodioritic intrusive rock. The mountain slopes are composed of bedrock of the Coast Plutonic Intrusive Group, as noted above. Shallow bedrock is composed of granite and granodiorite. The upper bedrock surface dips steeply from north to south into the subsurface across the site, from at or near the surface at the toe of the mountain slopes, descending to a depth of approximately 60m below the surface at the mouth of Mill Creek. A stiff, silty indurated layer with gravel and cobbles has been observed at the bedrock interface, which may be basal till that pre-dates glaciofluvial and glaciolacustrine sediments.

From the base of the adjacent mountains, there is a gentle slope towards Howe Sound across an alluvial fan where the Project is situated. Sediment increases in thickness from north to south. The slope is comprised of unconsolidated sediments consisting of fine-grained or mixed grain sediments of glaciofluvial or glaciolacustrine origin, along with various fill material (concrete, construction debris). The natural topography within the CPA has been altered by grading and filling as part of the historic development of the site and ongoing construction.

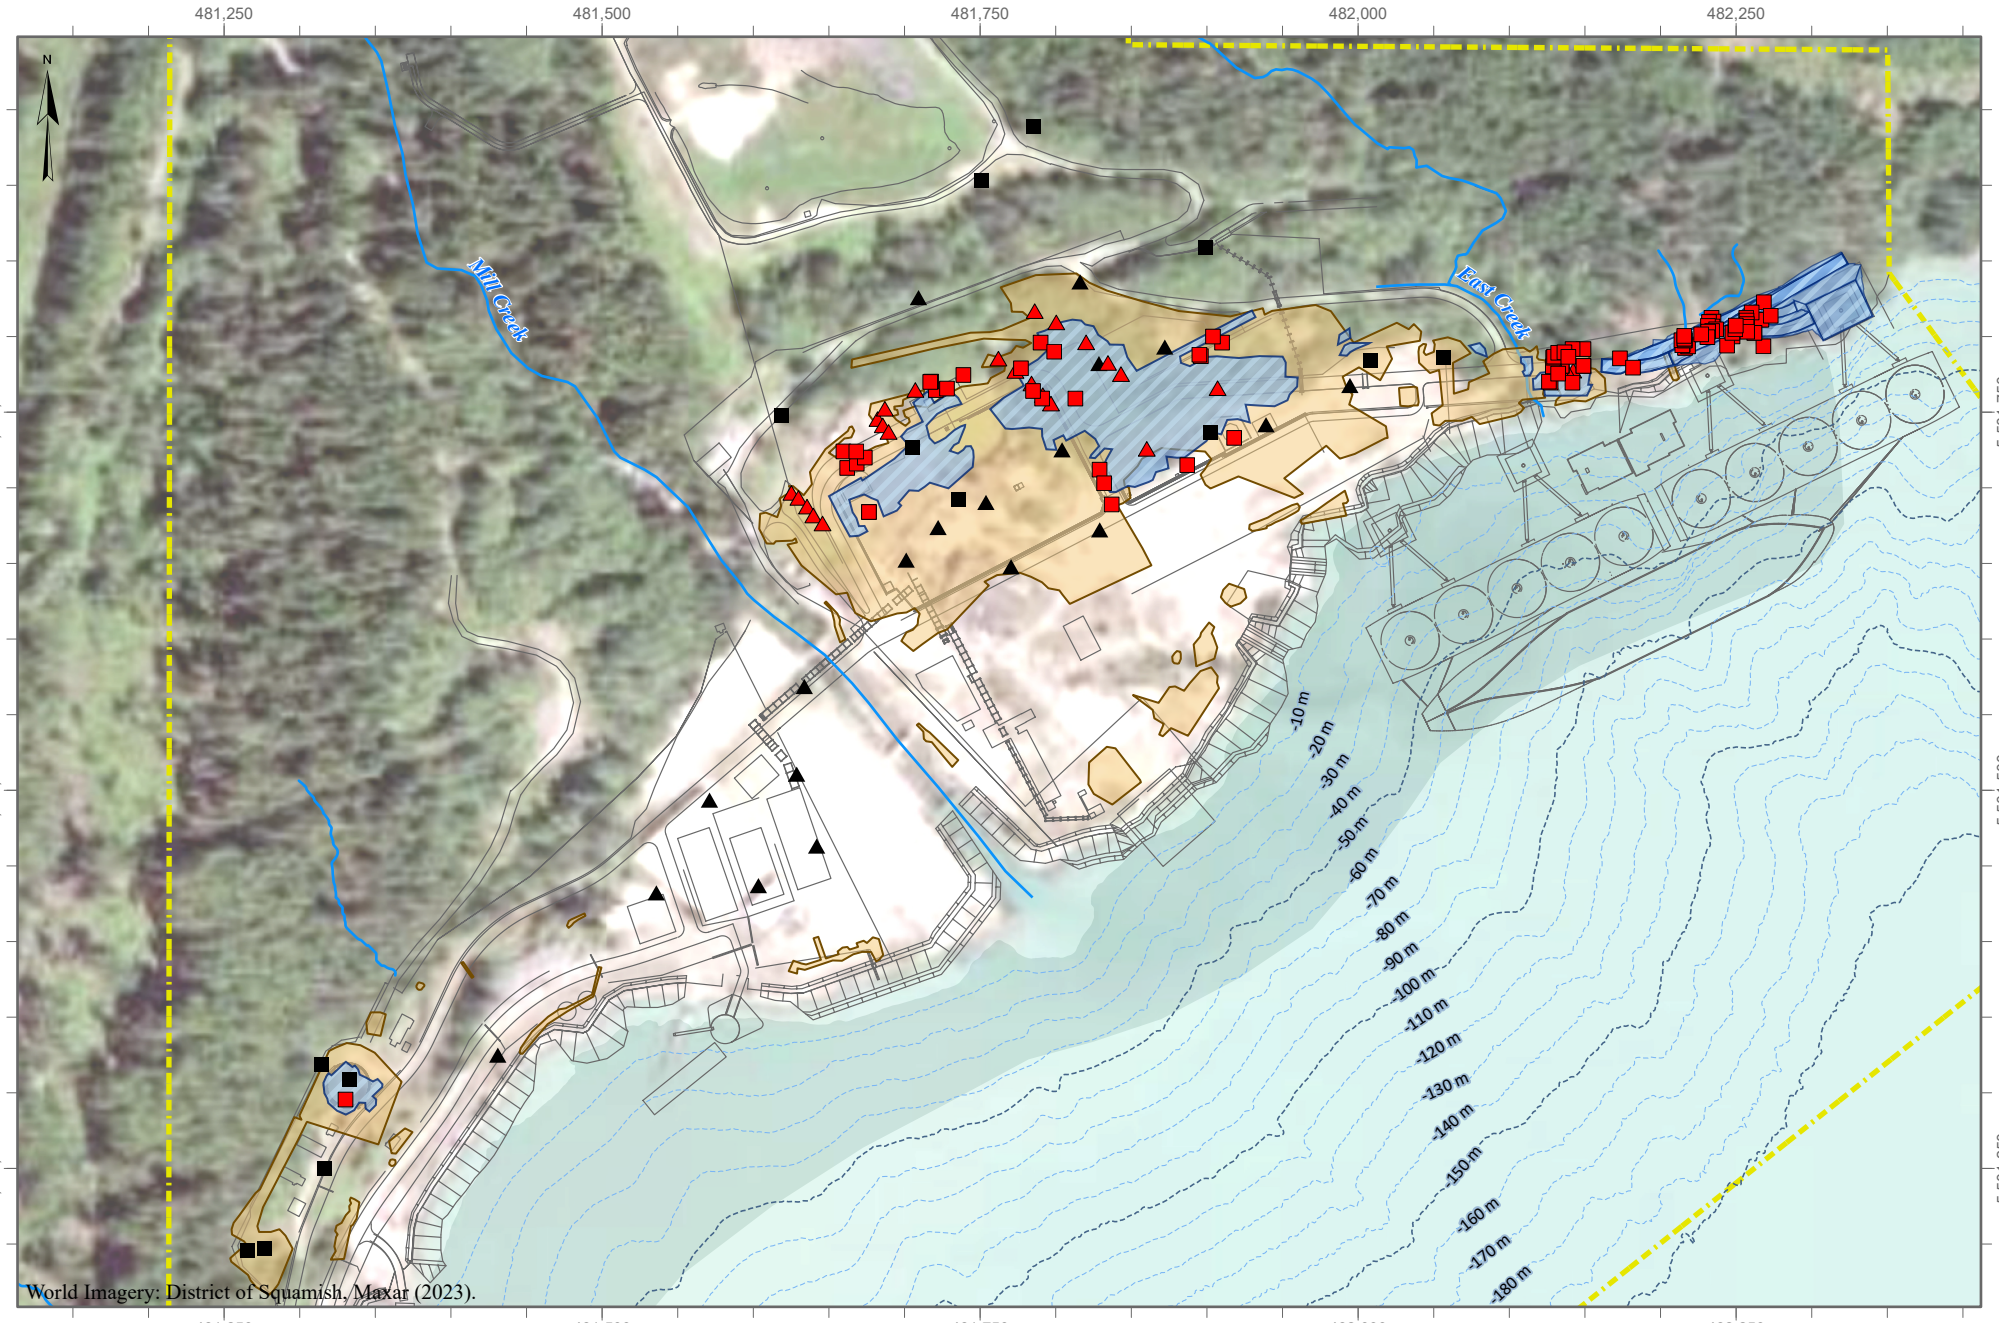
3.3.2 Construction Phase Excavations and Fill Placement

This section summarizes records of overburden and bedrock excavated during construction from November 2023 to August 2025. Geochemical monitoring records and spatial extents of overburden and bedrock excavations were provided by Roe Environmental Limited and McDermott International Limited. The areas where overburden and bedrock were excavated and geochemical samples were collected are shown in Figure 3-3.

3.3.2.1 Overburden Excavations

As described in Section 3.2.3, approximately 297,000 m^3 of overburden was excavated during construction from November 2023 to August 2025. Approximately 152,000 m^3 of overburden was exported from site as of August 2025, and approximately 180,000 m^3 was

re-used as fill. The overburden sample test results indicate the re-used material was geochemically suitable for use as fill.



3.3.2.2 Bedrock Excavations

Approximately 102,000 m^3 of bedrock was blasted and excavated from November 2023 to August 2025 in the Process and Marine Terminal Areas, and the upper Industrial Area in the vicinity of the Firewater Tank. The excavated bedrock was reused for construction purposes. The material was tested and determined to be geochemically suitable for re-use by Lorax Environmental, the qualified professional for metal leaching and acid rock drainage evaluations.

3.3.2.3 Fill Placement

Fill has been sourced from on-site excavations and, where required, imported from off-site quarries. Bedrock and overburden geochemically suitable for re-use were crushed on-site to make aggregate that could be used for fill. As of August 2025, all of the Project construction area had been covered with fill to a depth of approximately 1 m or more.

Approximately 110,000 m^3 of aggregate has been imported as of August 2025 for civil site preparation from off-site B.C. quarries (Gilley's Quarry and Sechelt Mine, in Coquitlam and Sechelt, respectively) including clear crush, granular base, granular subbase, drain rock, pit run sand, and Type A and D aggregates. The geochemistry of the imported materials was assessed based on geochemical test results of representative samples collected by the quarry and mine owners. The fill material from both sources was determined to be geochemically suitable for construction use (Lorax, 2024a).

3.3.3 Geochemical Assessment

A baseline geochemical characterization and assessment was completed by Stantec (2022a) of site bedrock and overburden, which is further discussed in the Lorax (2024a) Bedrock and Overburden Geochemical Characterization and Construction Phase ML/ARD Management Plan. The assessments determined the potential for acid rock drainage (ARD) for both bedrock and overburden is low. Similarly, bedrock exhibits low potential for metal leaching (ML). However, the laboratory shake flask extraction (SFE) test method identified a Cu leaching potential in a small proportion of overburden samples.

Confirmatory geochemistry sampling and testing of overburden and bedrock was conducted prior to excavated materials being re-used for fill during construction. Material excavated to the end of August 2025 that was determined to be geochemically suitable has been used as fill in the construction site. Results from samples collected from November 2023 to August 2025 are tabulated in Appendix 3.3-1. In summary, a total of six (6) overburden and 82 bedrock samples were collected and tested for acid base accounting (ABA), solid phase elemental analysis, and SFE elemental analysis.

3.3.3.1 ARD Potential

The combined ABA test results indicate that the overburden is not potentially acid generating (Table 3-3). The overburden material exhibits:

- Circumneutral paste pH (median = 7.1);
- Low sulphide S content (median =0.025 %);
- Generally low neutralization potential (NP; median = 9.3 kg $CaCO_3$/t); and
- Neutralization potential ratio (NPR) > 2.0 in more than 75% of the samples.

Similarly, bedrock material is also classified as not potentially acid generating (Table 3-4). The bedrock confirmatory samples exhibit:

- Circumneutral to slightly alkaline paste pH (median = 8.3);
- Low sulphide S content, generally below the method detection limit (median = <0.010 %);
- Low NP (median = 2.7 kg $CaCO_3$/t); and
- NPR > 2.0 in more than 75% of the samples.

The overburden and bedrock samples that were tested and assessed during excavations to the end of August 2025 were classified as not potentially acid generating. These results are consistent with the baseline geochemical assessment (Stantec, 2022a; Lorax, 2024a).

Table 3-3:
Summary of ABA Results for Confirmatory Overburden Samples

	Paste pH	Total S	Sulphide S	AP	Carbonate NP	Modified NP	NPR	CaNPR

NPR = Modified NP/AP
CaNPR = Carbonate NP/AP

3.3.3.2 Metal Leaching Potential

The metal leaching potential was evaluated using SFE testing. The results were compared to upper estimates of seepage source chemistry for overburden and bedrock (Lorax, 2024a) as well as the Canadian Council of Ministers of the Environment (CCME), Environment and Climate Change Canada (ECCC), and B.C. Marine Water Aquatic Life (MWAL) water quality guidelines (WQGs). When considering SFE results, it is important to note the sample was crushed into a fine powder as part of the analysis. This increases the material surface area available for leaching. Therefore, the SFE test may overestimate the leachability of the tested material compared to leaching from the larger grain size of materials that are re-used for construction purposes.

Generally, overburden SFE results for confirmatory overburden samples collected during construction are consistent with the pre-construction observations (Stantec, 2022a; Lorax, 2024a) and below the screening criteria established in the ML/ARD Management Plan. With the exception of copper for all overburden samples and vanadium for select samples, the overburden SFE leachate results were below WQGs for the protection of MWAL (Table 3-5). Mercury was not detected in the samples; however, the detection limit was above the WQG. Therefore, the SFE mercury results could not be evaluated against the mercury WQG.

As with overburden samples, the bulk of bedrock sample SFE leachate results were consistent with the results of the Stantec (2022a) study and below the ML/ARD Management screening criteria. Confirmatory bedrock SFE results are, generally, below WQGs for the protection of MWAL (Table 3-6). Maximum concentrations of copper, lead, and vanadium in bedrock SFE leachate samples are above the WQGs in <7%, <2% and <3% of bedrock samples, respectively, and overall are not considered to be parameters of concern in bedrock. Mercury was not detected in most bedrock samples, with the exception of five samples (6% of the samples), that are slightly above the detection limit, and above the WQG. The detection limit for mercury is above the WQG and is a limitation of the analytical method. The detected mercury concentrations in SFE leachates are likely in part due to analytical variability as the concentrations are close to the detection limit of the analytical method; therefore, the metal leaching potential for mercury in bedrock cannot be appropriately assessed from SFE testing. It is important to note that this should be considered a screening exercise and is not intended to provide quantitative water quality predictions. Given the infrequent detection of mercury in bedrock samples (<6%), overall mercury is not considered to be a parameter of concern in bedrock.

Table 3-5:
Summary of SFE Results for Confirmatory Overburden Samples

Parameter	Unit	Federal WQG	B.C. WQG	Min	P10	P25	Median	P75	P90	Max	Count

Consequently, as the majority of overburden and bedrock samples exhibited SFE leachate concentrations that were low and below the criteria outlined in the ML/ARD Management Plan (Lorax, 2024a) and the Federal and B.C. WQG for the protection of MWAL, these materials are considered to have a low metal leaching potential. The confirmatory bedrock SFE results are consistent with the baseline geochemical assessment (Stantec, 2022a and Lorax, 2024a).

3.4 Climate and Meteorology

Climate in southwestern B.C. is characterized by an annual cycle, where there is a rapid onset of wet weather in the autumn, which persists through the winter, with a gradual transition in spring months to warm, dry summers.

In winter, the jet stream conveys a steady progression of storms that originate in the Pacific Ocean onto the coast of B.C. Orographic lift causes these systems to rise over the Coast Mountains, cooling the air mass resulting in abundant precipitation. The dominant winter flow from the west and southwest also conveys relatively mild air into the region, relative to the high latitude of the Project site. In general, winter precipitation on the southwest coast falls as snow at elevations above 1,000 m, where a deep snowpack often accumulates, and falls as rain at elevations below 500m, where there is a maritime influence, with alternating rain and snow at elevations in between. This weather pattern is intensified by the effects of the El Niño Southern Oscillation (ENSO) in some years.

This generally mild, wet weather pattern is occasionally interrupted when high pressure systems descend from the western Arctic, resulting in outflow winds that convey cold, dry air from the interior to the coast. This usually lasts for a few days, although it may persist for up to two weeks or more. When storms from the Pacific move into these conditions, the interaction of mild, moist air from the Pacific and cold, dry air from the interior can result in snowfall at low elevations, and a snowpack may persist, even at sea level, for as long as air temperatures remain cold.

The steady stream of storms from the Pacific Ocean gradually abates in spring months, marked by a steady decrease in monthly precipitation, and gradual rise in mean monthly temperature, from February to July.

Summer weather is dominated by the northward migration of the North Pacific High, a semi-permanent, subtropical anticyclone located in the northeast Pacific Ocean. Once it has moved to its northerly position west of B.C. in summer months, it dominates weather patterns in the region, resulting in a warm, dry, Mediterranean climate. This typically lasts from early summer to early autumn.

Hourly averages of air temperature, precipitation, barometric pressure, relative humidity, wind speed and direction are measured at an on-site meteorological station located within the Project site along the foreshore, just east of the mouth of Mill Creek (Figure 3-4). Data collection began on April 28, 2022, and is ongoing; a summary of the measured data is provided herein. Table 3-7 lists the components of the on-site meteorological station (Stantec, 2025).

Notes:
Reproduced from Stantec, 2025.
The location selected for the WLNG meteorological station meets the requirements listed in the Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators (B.C. ENV, 2016). The station is required to be placed in an open level area with unobstructed wind flow.
[1]A RM Young 05305 air quality wind sensor replaced the RM Young 05108L40 heavy duty wind sensor on November 28, 2024.

Long-term climate data from the Environment Canada Squamish Airport Station (ECCC, 2025a) are used as a proxy for historical climate patterns within the Project site. The Squamish Airport Station is located approximately 15 km northeast of the Project site in Squamish, B.C., roughly 11 km upstream from the mouth of the Squamish River. The climate stations and parameters summarized in this section are outlined below in Table 3-8. The location of these stations in relation to the CPA are shown in Figure 3-4.

The following discussion summarizes the data collected at the WLNG Meteorological Station and the 1991-2020 Canadian Climate Normals for the Squamish Airport Station (ECCC, 2025b).

[A] Records were evaluated to the end of 2024, the last full year of records that were available at the time of preparation of this report.

3.4.1 Air Temperature

Air temperature measurements collected at the WLNG Meteorological station and at Squamish Airport Station from April 2022 to December 2024 followed similar trends, with temperatures at Squamish Airport showing a slightly wider range than those recorded at the WLNG station (Figure 3-5).

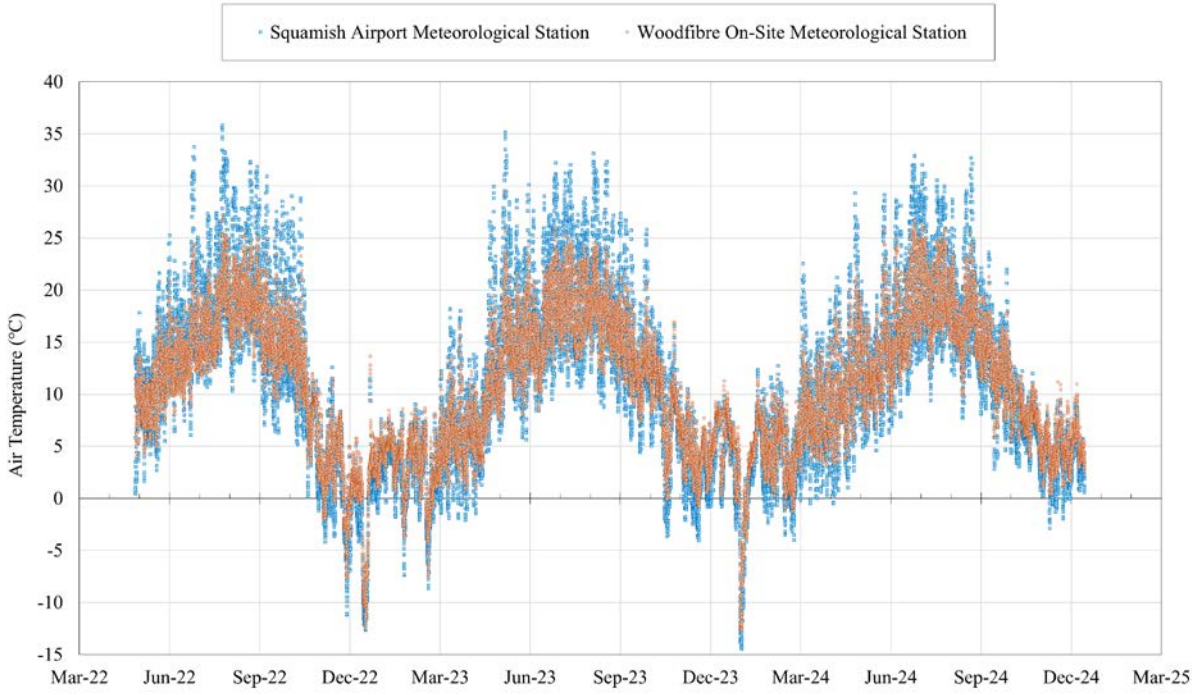

Figure 3-5: Hourly Air Temperature at WLNG Meteorological Station and Squamish Airport Station from April 28, 2022 to December 31, 2024

The 2022 to 2024 hourly temperature measurements follow the long-term annual trends of the mean daily temperatures observed at the Squamish Airport Station from 1982 to 2024, as shown by the statistical summary presented in Figure 3-6. The mean daily temperature varies significantly throughout the year, with the monthly average mean daily temperature ranging from 1.2°C (December) to 18.4°C (July and August). Overall, the mean daily

temperature decreases rapidly in autumn, followed by a more gradual warming trend from late winter through early summer.

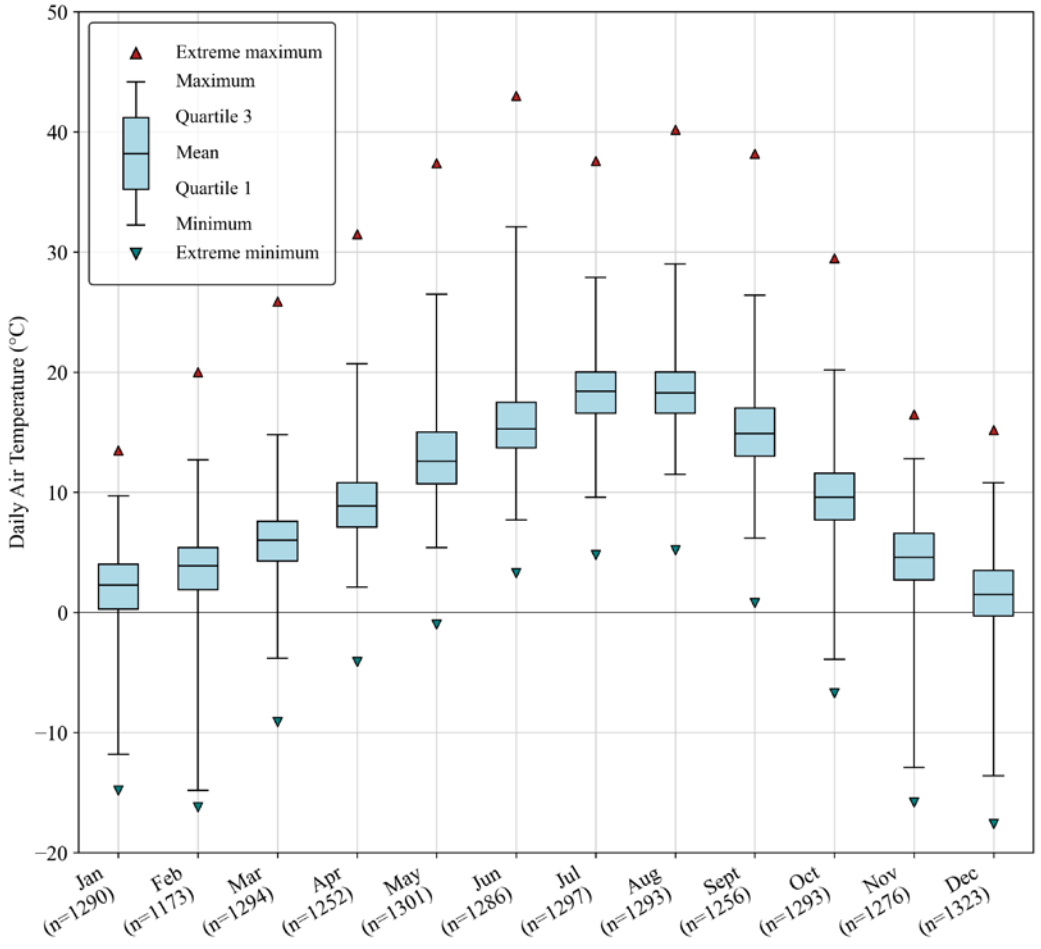

Figure 3-6: Mean Daily Temperature Statistical Values for Squamish Airport Station and Extreme Values (1982 to 2024)

While mean daily temperature provides a good indication of general trends with the predominant influence of maritime conditions, daily extreme minimum and maximum values reflect the full range of temperatures that have been observed at the Squamish Airport Station. The extreme values are the highest maximum and lowest minimum daily temperatures observed over the 1982 to 2024 period, and these values are also shown in Figure 3-6.

The extreme minimum values illustrate the effects of temporary arctic outflow conditions in winter months, and extreme maximum values reflect the influence high pressure system heat domes that may establish in the summer months. While the monthly average mean daily temperatures remain above 0°C year-round, sub-zero extreme daily minimum temperatures have occurred from October through May, with the extreme minimum

temperatures ranging from -1.0°C to -17.6°C during the October to May period. The highest extreme maximum temperatures, ranging from 37.4°C to 43.0°C were observed in the months of May to September.

3.4.2 Precipitation

The statistical values for total monthly precipitation at the Squamish Airport Station also show a strong seasonal pattern as illustrated in Figure 3-7. Over the 1982 to 2024 period, the lowest mean total monthly precipitation values are observed from May to September (95 to 107 mm) and the highest monthly precipitation values are from October through March (211 to 396 mm) with the highest monthly precipitation totals typically occurring in November. The primary driver of high-magnitude, multi-day rainfall events in Squamish are atmospheric rivers, which are long and narrow bands of water vapor in the atmosphere (Legarth *et al.*, 2025). Atmospheric rivers can cause extreme flooding events when they pass over mountainous terrain as they are forced upwards by the landform, ultimately forming clouds and causing periods of high intensity precipitation.

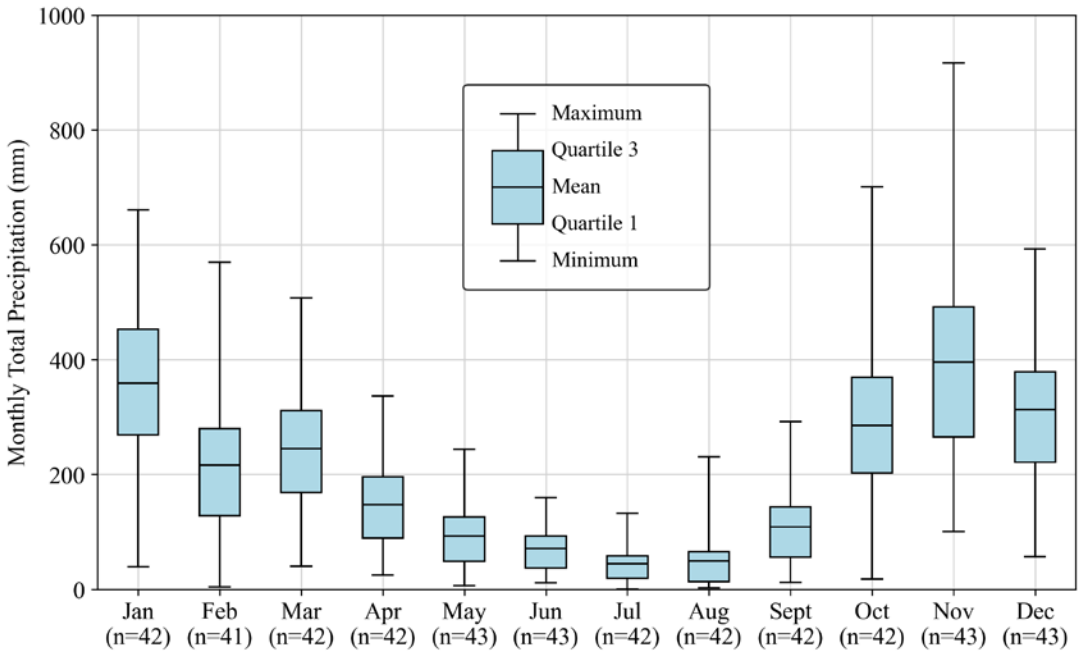

Figure 3-7: Total Monthly Precipitation Statistical Values for Squamish Airport Station from 1982 to 2024

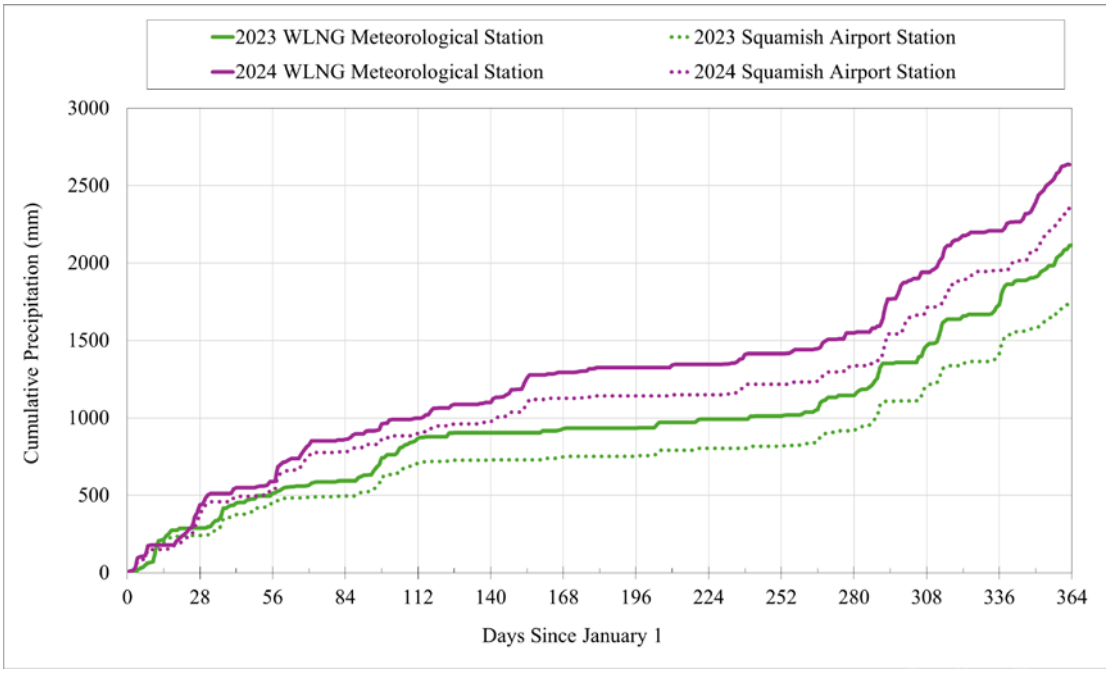
Cumulative precipitation trends between the CPA and Squamish Airport were similar in 2023 and 2024; however, the WLNG Meteorological Station received approximately 20% more precipitation compared to the Squamish Airport Station in both years (Figure 3-8).



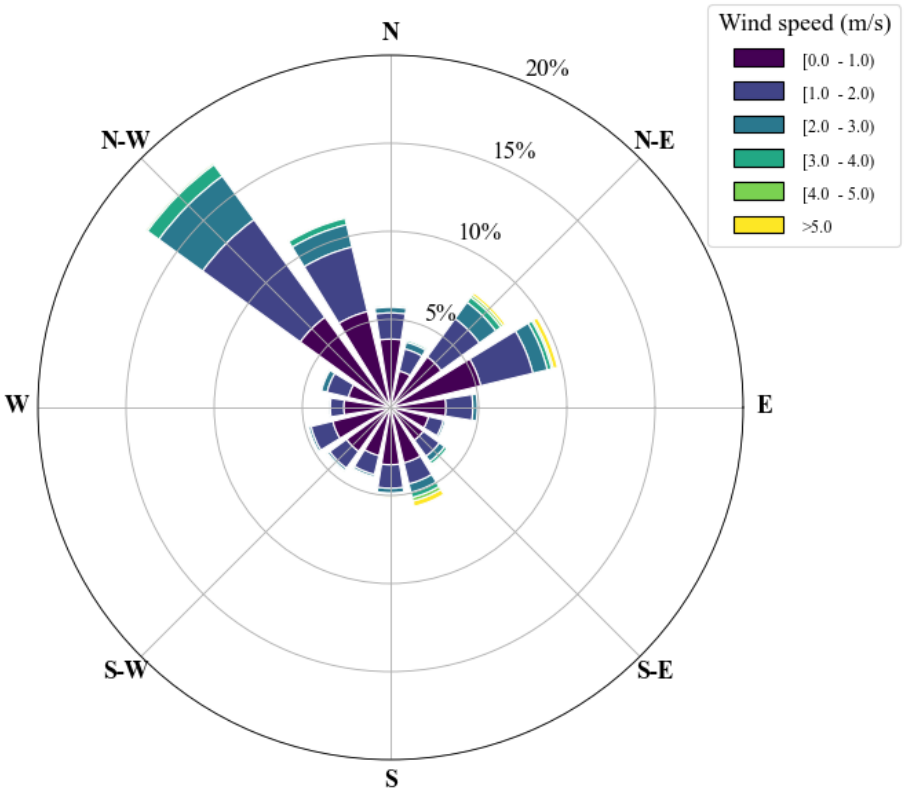


Figure 3-8: Cumulative Precipitation at WLNG Meteorological Station and Squamish Airport Station (2023 and 2024)

3.4.3 Wind

Strong winds are often experienced in the Project area due to a temperature gradient between the Strait of Georgia and mountain valleys to the north and is amplified by local topography. The regional topography results in diurnal winds forming due to the absorption of radiant heat by the ocean in contrast with more pronounced heating or cooling of air over the land surface to the north. This is strengthened by the Venturi effect (increased wind speed as winds are drawn through a narrow passage), as Howe Sound and the Squamish River valley are oriented north-northeast to south-southwest and are bounded by steep mountains to the west and east.

The resulting winds are katabatic (or 'outflow') in winter, when the air over Howe Sound is warmer, and therefore rises more quickly, than air over the land to the north. Wind speeds reach greater than 5 m/s from the north-northeast in winter. Winds are anabatic (or 'inflow') during warm, summer days, when the air over the land surface to the north is warmer, and therefore rises more quickly, than the air over the ocean to the south. Wind speed periodically ranges from 3-10 m/s from south-southeast in summer. Monitoring results from the WLNG meteorological station collected from April 2022 to December 2024 indicate the predominant wind direction and highest wind speeds at the Project site are from the northwest suggesting the Mill Creek valley exerts a strong local influence (Figure 3-9).

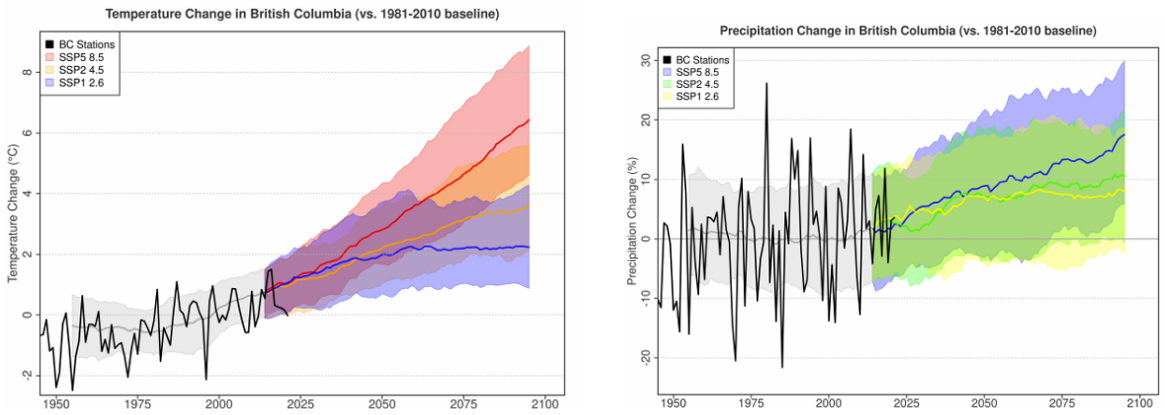
Notes: The brackets and parentheses next to wind speed values in the legend indicate those values are included and excluded, respectively, in that range of values.

Figure 3-9: Wind Rose for the WLNG Meteorological Station from April 2022 to December 2024

3.4.4 Evaporation

The rates of evaporation at the WLNG Meteorological Station were obtained from a climate model for B.C. that was developed at the University of British Columbia (UBC, 2022). The model is based on 1991 to 2020 Climate Normals data (Wang *et al*, 2016). The model results for the location of the WLNG Meteorological Station indicate that mean monthly evaporation ranges from 8 mm in December to 114 mm in July and is directly related to the seasonal changes in air temperature, with higher rates of evaporation occurring during the summer months. The modelled mean monthly evaporation rates are shown in Table 3-9.

Table 3-9:
Modelled Mean Monthly Evaporation at WLNG Meteorological Station (UBC, 2022)



Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Evaporation (mm)	10	19	37	63	94	102	114	97	62	30	13	8

Note: Evaporation was modelled using the coordinates of the WLNG meteorological station (UTM 481618 E, 5501354 N).

3.4.5 Climate Change

Air temperatures and precipitation are expected to continue increasing globally and in B. C. A study by Picketts & Hamilton (2016) forecasts that the District of Squamish will warm by 1.7°C and experience a 6% annual increase in precipitation by the 2050s, along with a significant decrease in snowfall.

Similar observations were made in study by Curry & Sobie (2023) which compared historical air temperature and precipitation measurements from climate stations in B.C. with projections from three different global models published by the Intergovernmental Panel on Climate Change, as shown in Figure 3-10. Each model assumed a different amount of future global greenhouse gas emissions, with SSP1 2.6 assuming a large reduction in emissions, SSP2 4.5 a moderate reduction in emissions, and SSP5 8.5 a high-emissions scenario (continued use of fossil fuels with no reduction in emissions; IPCC, 2023). All three scenarios predict an increase in air temperature and precipitation in B.C. by 2100, with the SSP5 8.5 projection predicting the greatest increase in temperature and precipitation and the SSP1 2.6 projection predicting the least (Curry & Sobie, 2023).

Note:
Figures reproduced from Climate Projections for the City of Vancouver: Highlights Report, page 7 (Curry & Sobie, 2023). The coloured lines represent median values within each model projection. The shaded areas represent the 10th to 90th percentile of each model projection for both historical and future values. The black lines show station data collected in B.C. from 1948 to 2021.

Figure 3-10: Comparison of Historical Air Temperature and Precipitation in British Columbia to Global Climate Model Scenarios (Curry & Sobie, 2023).

3.5 Hydrology

3.5.1 Watershed Characteristics

The Project is adjacent to the lower extent of the Mill Creek, Woodfibre Creek, and East Creek watersheds that discharge to Howe Sound at the Project site as shown in Figure 3-1. These watersheds are densely vegetated, have been previously logged and have negligible glacial coverage. Additional information with respect to the hydrometric monitoring

program and derived data summaries for the Woodfibre and Mill Creek watersheds are described in the Woodfibre Hydrometeorological Baseline Report (Stantec, 2020).

The Mill Creek watershed is the largest of the three watersheds (40.8 km^2) and contains the highest elevation contributing areas (refer to Table 3-10), as well as a lake (Scott Lake) located at 1,300 m that comprises less than 1% of the total catchment area. The Mill Creek stream channel spans approximately 9 km from its source near Mount Sedgwick to the confluence with Howe Sound, with an average gradient of 7.5%. Channel gradients are steepest in the headwaters, moderate at mid-elevation, and steeper in the lower reaches (10%). The channel gradient slackens to 4% at within the CPA where it flows over an alluvial fan (Knight Piésold, 2019b). Mill Creek is fish-bearing and is characterized by upstream freshwater conditions and downstream estuarine conditions. Cascade pool morphology and steep falls are observed in the upper reaches, while the lower reach that bisects the Project area has been channelized with riprap armouring the southern bank. The estuarine segment of Mill Creek overlaps with the industrialized portion of the Project site and is within the riparian reserve zone downstream of the third bridge, which represents the extent of tidal influence in the creek (Keystone, 2021b). A historical water diversion intake is located on Mill Creek upstream of the Project boundary. The diversion structure directs a portion of the Mill Creek flows to the intake of a pipeline that conveys water to the Project site and was used as water supply for the historical pulp mill.

The Woodfibre Creek watershed has a catchment area of 21.8 km^2 and ranges in elevation from sea level to 1,600 m (refer to Table 3-10). The watershed contains five lakes: Henriette Lake, Sylvia Lake, Woodfibre Lake and two smaller unnamed lakes (Knight Piésold, 2019a). Henriette Lake is the largest, and its catchment area accounts for approximately 37% of the total Woodfibre Creek watershed area (Stantec, 2020). Henriette Lake has a control structure (forming a dam) that influences the flow regime in the Woodfibre Creek watershed, and has higher summer flows and lower freshet flow in comparison to Mill Creek (Knight Piésold, 2019a). The Woodfibre Creek stream channel spans approximately 6.8 km^2 from its source near Woodfibre Lake to the confluence with Howe Sound. Channel gradients average 15%, and remain steep throughout the creek's length, with a small alluvial fan at its outlet (Knight Piésold, 2019a). The creek bed is characterized by large boulders, cobbles, and gravel which may provide salmonid spawning habitat. Anthropogenic influence, including rebar and concrete foundations from historic pulp mill operations, has been observed on the banks of the lower segment of the creek (Keystone, 2021b).

East Creek is located on the northern periphery of the Project area, approximately 450 m northeast of Mill Creek (Keystone, 2021b). The East Creek watershed is approximately 0.6 km^2 and ranges in elevation from sea level to 900 m (refer to Table 3-10), with no lakes,

and an average gradient of 13%. East Creek has two main tributaries. The upper tributary runs through forested areas, upslope of a historic fill area, and descends through a series of steep cascades to Howe Sound at an average gradient of 13%. The lower tributary passes through a constructed channel beside a road downslope of the historic fill area. East Creek flows into a culvert beneath the service road along the shoreline before discharging into Howe Sound (Keystone, 2014a).

Table 3-10:
Watershed Areas and Elevations

Watershed	Catchment Area (km^2)	Watershed Elevation (m asl)		
		Min	Mean	Max
Mill Creek	40.8	0	975	2,000
Woodfibre Creek	21.8	0	928	1,600
East Creek	0.6	0	300	900

3.5.2 Hydrometric Data

Hydrometric data has been collected intermittently in the local catchments as early as 2009 (Mill Creek and Woodfibre Creek) and starting in 2019 in the East Creek catchment (Stantec, 2020). The following discussion summarizes the results of the Woodfibre Hydrometeorological Baseline Report (Stantec, 2020) and the results from monitoring records collected from 2021 through 2025. Local and regional hydrometric stations, and the period of record for each station are listed in Table 3-11, and the locations are shown in Figure 3-4.

Knight Piésold deemed the 2009-2010 and 2017-2025 streamflow record for Mill Creek, and the 2017-2025 record for Woodfibre Creek reliable, with most variables receiving a data grade of 'A' with some limited exceptions per the B.C. RISC standards ENV (2018) as outlined by Knight Piésold (2025a,b). The data available at the time the Stantec (2020) baseline report were analysed along with regional hydrometric data from the Water Survey of Canada Capilano River above Intake station to generate longer-term synthetic timeseries of streamflow and flow statistics (Stantec, 2020; Knight Piésold, 2019a,b).

Table 3-11:
Regional and WLNG Site Hydrometric Stations

Network	Station Name	Station ID	Record Period	Catchment Area (km^2)
Water Survey of Canada	Capilano River Above Intake [1]	08GA010	1914-2025	173

	East Creek	EAST	2019-2020	0.2-0.5 [2]

Notes:
[1] The record from this station was used to develop long-term daily synthetic streamflow records for Mill Creek and Woodfibre Creek (Knight Piésold, 2019a,b).
[2] Stantec (2020) installed flow monitoring equipment in East Creek downstream of the landfill area in 2019. The exact location and drainage area of the monitoring location is not specified by Stantec (2020). The landfill is approximately 400 m upstream of the mouth of East Creek.

3.5.3 Mean Annual Runoff and Monthly Distribution

As described in Section 3.4, precipitation at the Project site follows a seasonal pattern, with greater precipitation in the winter months, and relatively drier conditions persisting throughout the summer months. While winter precipitation is dominated by snowfall at the higher elevations within the local catchments, elevated freezing levels can result in rain or snow to the highest elevations. This can result in rain-on-snow events at the Project site that drive annual maximum stream flows during the winter months, and primarily during the months of October to February.

Mean annual runoff has been estimated to be 2,881 mm in Mill Creek and 3,987 mm in Woodfibre Creek (based on long-term synthetic streamflow timeseries; Knight Piésold 2019a and 2019b). The difference in runoff between these two watersheds is attributed to local orographic and wind shadow effects that significantly influence runoff amounts between adjacent watersheds in the region (Stantec, 2020). East Creek drains a small watershed adjacent to Mill Creek and runoff is estimated to be similar to Mill Creek

(2,881 mm; Stantec, 2020). Mean annual discharge in Mill Creek, Woodfibre Creek and East Creek watersheds are estimated to be 3.73 m^3/s, 2.76 m^3/s and 0.06 m^3/s, respectively (Stantec, 2020). Due to the Henriette Lake dam outlet control on the discharge regime of Woodfibre Creek, the synthetic streamflow record developed by Knight Piésold (2019b) for Mill Creek is used here to represent the local unregulated streamflow regime within the Project site.

Mill Creek and East Creek are estimated to have similar monthly runoff distributions with the higher flows occurring in April through June with May being the highest average month (Stantec, 2020; Figure 3-11 and Figure 3-12). Monthly average runoff data from the nearby Stawamus River hydrometric station operated by the Water Survey of Canada (station 08GA076; 52.8 km^2) are provided for reference and show good correspondence with the long-term streamflow record developed for Mill Creek, albeit with lower freshet runoff due to its lower median elevation and therefore, lower snowpack. The monthly distribution in Woodfibre Creek is estimated to have a slightly delayed high flow, compared to the other two watersheds, with June being the highest average month and elevated flows in October and November.

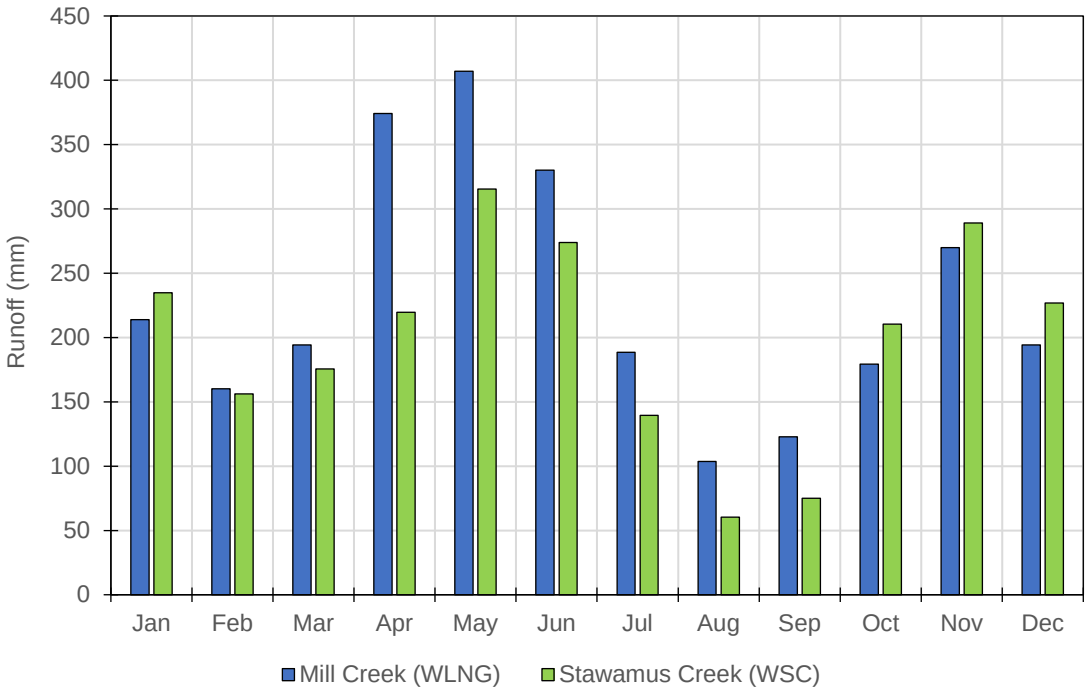

Figure 3-11: Monthly Runoff Distribution for Mill Creek and the Stawamus River at Highway 99 Water Survey of Canada gauges

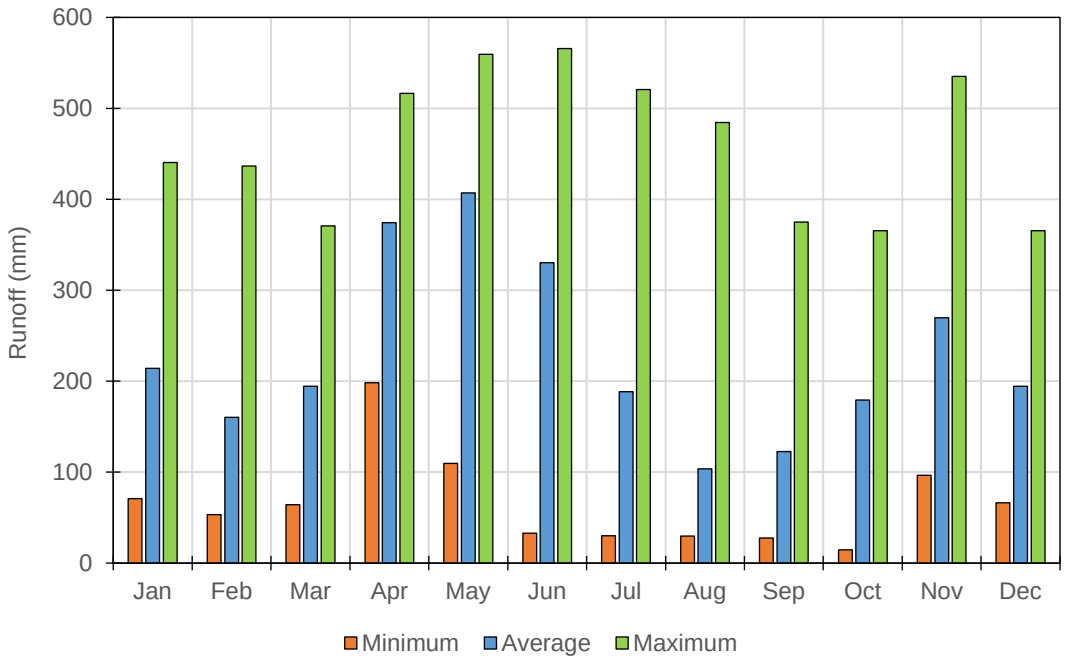

Figure 3-12: Minimum, Mean and Maximum Monthly Runoff Distribution for Mill Creek

3.5.4 Peak Flows and Low Flows

Estimates of extreme low flows (based on a 7-day rolling average streamflow) and peak flows (instantaneous, or 15-minute maximum) are required to set limits on allowable withdrawals from local streams, or other reductions in streamflow (*e.g.*, alteration of contributing catchment area), and for the design of water management infrastructure to convey and withstand high-magnitude flow events, respectively.

The minimum annual seven-day average flow with a 10-year return period (annual $7Q_{10}$) is estimated to be 0.19 m^3/s for Mill Creek (refer to Table 3-12). The minimum June to September seven-day average flow with a 10-year return period (June to September $7Q_{10}$) for Mill Creek is estimated to be 0.26 m^3/s (Stantec, 2020). These values are used as indicators of extreme low flow conditions.

Estimates of instantaneous peak flows were derived by Stantec (2020) using multiple methods, and the values derived from the regional analysis are presented in Table 3-13.

Table 3-12:
Minimum, Mean and Maximum Mean Monthly Runoff and Discharge Estimates for Mill Creek

Month	Runoff (mm)			Discharge (m^3/s)		
	Minimum	Average	Maximum	Minimum	Average	Maximum
Jan	71	214	440	1.08	3.26	6.71
Feb	53	160	437	0.81	2.44	6.65

100-year	150	94	6.3
200-year	160	100	6.7

3.6 Surface Water Quality

As described in Section 3.5.2, Mill Creek, Woodfibre Creek and East Creek discharge to Howe Sound within the Project site. In addition, stormwater runoff (*i.e.*, non-contact water) from the hillslopes above the Project site is intercepted by diversion ditches that discharge to Howe Sound or Mill Creek. Flow is observed in the creeks year-round. However, diversion ditches only contain running water during rainy periods with flows most frequently observed from October to May.

The water quality of Mill Creek and diversion ditches have been monitored at various locations and frequencies since 2006. Monitoring periodically occurred between 2006 to 2013 as described in the construction WDA technical assessment report (Lorax, 2023). Regular monitoring commenced in August 2018, and was expanded to include diversion ditch stations in 2022. The water quality results from August 2018 through May 2025 are considered a comprehensive representation of water quality prior to LNG facility operation and the limited number of samples collected prior to 2018 are excluded from the dataset presented herein. The water quality results for individual samples are tabulated in Appendix 3.6-1.

3.6.1 Surface Water Quality Monitoring Programs

A total of 745 surface water monitoring samples were collected from August 2018 to May 2025. The monitoring station locations are shown in Figure 3-13 and a description of the monitoring stations is provided in Table 3-14. Of the 745 monitoring samples, 544 were collected from downstream monitoring stations located near the mouth of Woodfibre, Mill and East Creeks (*i.e.*, SW-01, SW-02, SW-03 and SW-04) and 154 were collected from upstream background monitoring stations (*i.e*., SW-08, SW-07 and SW-09) on the same creeks. The remaining 77 samples were non-contact water from within the diversion ditches (SW-05 and SW-06) or at the outlet of the ditches (OUT-01, OUT-02 and OUT-06). The surface water quality sampling programs are summarized below:

- WLNG commenced pre-construction quarterly sampling in August 2018 at Mill Creek (SW- 03) and Woodfibre Creek (SW-01) stations. Monthly monitoring commenced in January 2021 and expanded the monitoring network to include an additional station on Mill Creek (SW-02) and a new station at East Creek (SW-04). The diversion ditch stations (SW-05 and SW-06) were monitored from April 2022 to December 2023, when there was water in the ditches. The Mill Creek background station (SW-07) was added to the program in August 2023.
- Surface water monitoring has continued since construction commenced at stations SW-01, SW-02, SW-03, SW-04 and SW-07. Monitoring of the diversion ditch stations SW-05 and SW-06 was discontinued in January 2024. Background stations were added for Woodfibre Creek (SW-08) and East Creek (SW-09) in April 2024.
- Monitoring in accordance with WDA Effluent Permit PE-111578 commenced April 2024, and has included stations SW-01, SW-02, SW-03, SW-04, SW-07, and diversion ditch stations OUT-01, OUT-02 and OUT-06. The SW-06 station was also monitored in February and March of 2025.

Table 3-14:
Surface Water Quality Monitoring Stations

Station	Latitude	Longitude	Description
SW-01	49.661392	-123.258933	Lower reach of Woodfibre Creek (near mouth)
SW-02	49.667981	-123.256544	Lower reach of Mill Creek (upstream of third bridge)
SW-03	49.665219	-123.252525	Mill Creek estuary
SW-04	49.668044	-123.247828	Lower reach of East Creek (near outlet to the outfall culvert)
SW-05	49.662462	-123.259216	Watercourse P1 (non-contact diversion ditch) at the culvert inlet
SW-06	49.664586	-123.258327	Tributary 1 (non-contact diversion ditch), northeast of the confluence with ditch D10
SW-07	49.679100	-123.266900	Upstream Mill Creek (at water intake)
SW-08	49.6673709	-123.2830505	Upstream Woodfibre Creek
SW-09	49.6716937	-123.2535137	Upstream East Creek
OUT-01	49.6618988	-123.2585679	Non-contact water diversion ditch outlet
OUT-02	49.66262905	-123.2585254	Non-contact water diversion ditch outlet
OUT-06	49.6668422	-123.2549651	Non-contact water diversion ditch outlet

The surface water quality monitoring programs generally included field measurements (*i.e.*, temperature, turbidity, conductivity, salinity, pH and dissolved oxygen) and analytical testing at accredited laboratories for physical parameters (pH, turbidity, total suspended solids [TSS], and total dissolved solids [TDS]), general parameters (nutrients and anions), total and dissolved metals, speciated metals (methylmercury, hexavalent and trivalent chromium), petroleum hydrocarbons, PAHs, VOCs, polychlorinated dibenzo-*p*-dioxins and polychlorinated dibenzofurans (PCDD/Fs) and *Escherichia coli* (E. coli).

Analytical testing was completed at laboratories accredited by the Canadian Association for Laboratory Accreditation Inc. (CALA) for the analyses performed, which use test methods that conform with ISO 17025 standards. The program switched laboratories at the start of 2024 and for most of the tested parameters, analytical detection limits have either decreased or remained the same with the change in analytical testing laboratories; therefore, higher detection limits are observed during the pre-construction surface water quality monitoring. It is noted that detection limit values for parameters reported as not detectable occasionally vary between samples due to changes in testing technology, or due to test interferences that reduce the sensitivity of a test method for a particular sample at the time of testing.

3.6.2 Quality Assurance and Quality Control

Collection of field quality control samples, including blank and duplicate samples, was initiated in January 2021 and February 2022 (respectively) and has continued as part of the standard monitoring suite. A total of 167 QA/QC samples, consisting of 91 blank samples (14 travel blanks and 77 field blanks) and 76 duplicate samples, have been collected, and represent 22% of the total number of monitoring samples (n=745) collected during the August 2018 to May 2025 period.

Overall, the blank sample evaluation indicates that 1.6% of all parameters tested in blank samples show concentrations above the detection limit value and 0.7% of detectable parameters show concentrations greater than two times the detection limit value. Metal species with multiple instances of detectable concentrations at a similar magnitude to the monitoring dataset include total Co, molybdenum (Mo), and methylmercury. However, these instances occur in less than 11% of all blank samples and monitoring data show low concentrations of these parameters relative to federal and provincial WQGs; therefore, the potential contamination indicated by the blank samples does not meaningfully alter the interpretation of the data or lead to misinterpretation of the monitoring results. Notably, select PAHs (benz(a)anthracene, benzo(a)pyrene, dibenz(a-h)anthracene, and quinoline) and a VOC compound (chloroform) show similar frequency of detection and magnitude of concentrations in blank samples relative to the monitoring dataset. In one field blank sample collected in August 2021, benz(a)anthracene and benzo(a)pyrene concentrations were detected at 2.6 and 2.3 times greater than the long-term WQGs (0.000018 mg/L and 0.000015 mg/L, respectively).

It is inferred that contamination associated with sampling supplies or field collection contributed to the elevated concentrations observed in blank samples. Therefore, monitoring results for benzo(a)pyrene, benz(a)anthracene, dibenz(a-h)anthracene and quinoline are inferred to reflect a higher degree of uncertainty compared to other parameters in the dataset. The source of chloroform contamination in blank samples is confirmed to be from deionized water supplied by the laboratory containing trace levels of chloroform that was used to fill the blank sample bottles; therefore, the interpretation of the monitoring data is not affected because deionized water is not added to environmental samples.

Relative percent difference calculated for field duplicate pairs demonstrates sufficient reproducibility as less than 2% of all duplicate parameter pairs show relative percent difference greater than 20% and less than 1% of all duplicate parameter pairs show relative percent difference greater than 50%. Total Fe, Mn and methylmercury concentrations account for multiple instances of relative percent difference values greater than 50%.

Anomalies in duplicate samples may reflect inherent sample variability and/or spatial variability of suspended particulate material. Overall, the duplicate results indicate the monitoring dataset is considered representative and reliable as more than 98% of duplicate parameter pairs are shown to be highly reproducible.

3.6.3 Surface Water Quality Results

The surface water quality dataset from August 2018 to May 2025 is considered representative of pre-operations surface water quality for the Project. Key observations and conclusions from August 2018 to May 2025 surface water quality monitoring results are described in the following sections, including comparison of results to federal and provincial WQGs, and evaluation of background pH conditions in the watercourses within and adjacent to the Project site. Statistical summary tables of key parameters for Woodfibre Creek, Mill Creek, East Creek and non-contact water diversion ditches are presented at the end of this section. The monitoring results for surface water samples are tabulated in Appendix 3.6-1.

3.6.3.1 Background pH Conditions in Freshwater

Background freshwater quality conditions are characterized using upstream monitoring stations for Woodfibre Creek (SW-08), Mill Creek (SW-07), East Creek (SW-09) and stations that monitor non-contact water conveyed by diversion ditches (OUT-01, OUT-02, OUT-06, SW-05 and SW-06). The creek background stations shown in Figure 3-13 are located above areas of historical disturbance. The non-contact water quality stations monitor stormwater runoff from hillslopes above the Project site that is intercepted by diversion ditches that were largely constructed within overburden gravels and is directed to Howe Sound or Mill Creek. The data collected at these stations are considered to be generally free of Project-related influence and representative of natural baseline conditions for creek water and stormwater runoff from forested areas.

Monthly field measurements summarized in Table 3-15 indicate that pH conditions are naturally mildly acidic to circumneutral, with observed background ranges of pH 5.63 to 6.49 in Woodfibre Creek (SW-08), pH 5.25 to 8.40 in Mill Creek (SW-07), pH 6.26 to 7.38 in East Creek (SW-09) and pH 5.60 to 8.20 in diversion ditch water (OUT-01, OUT-02, OUT-06, SW-05 and SW-06). The pH values frequently fall outside the lower limit of the B.C. WQG of pH 6.50. The observed values are comparable with the pH range of 5.4 to 7.6 for Cascade Mountains region reported in the B.C. pH Water Quality Guidelines (ENV, 2021). The Cascade Mountains region is characterized as "a high rainfall area" (150 to >350 cm/yr) that has fairly uniform granitic geology with thin soils, similar to the Project setting. The combination of slow weathering of the granitic rock and the high runoff

rates produces very dilute levels of carbonate in surface waters that contributes to low pH values.

Table 3-15:
Statistical Summary of Background pH Conditions in Fresh and Estuarine Water Quality Stations

Station	Description	No. Samples	Min.	P5	P10	Median	P90	P95	Max.
Woodfibre Creek									
SW-01	Lower reach of Woodfibre Creek	84	**5.41**	**5.54**	**5.77**	**6.45**	7.20	7.43	**9.10**
SW-08	Upstream Woodfibre Creek	14	**5.63**	**5.64**	**5.66**	**5.82**	**6.20**	**6.31**	**6.49**
Mill Creek									
SW-02	Lower reach of Mill Creek	79	**5.17**	5.66	6.03	6.70	7.38	7.61	8.40
SW-03[1]	Mill Creek estuary	82	**5.43**	**5.91**	**6.18**	**6.82**	7.93	8.05	8.60
SW-07	Upstream Mill Creek	54	**5.25**	5.52	5.69	6.38	6.90	7.14	8.40
East Creek									
SW-04	Lower reach of East Creek	86	**5.02**	6.54	6.83	7.46	7.90	8.00	8.30
SW-09	Upstream East Creek	22	**6.26**	**6.26**	**6.34**	6.92	7.10	7.13	7.38
Non-contact water[2]									
SW-05, SW-06, OUT- 01, OUT-02, OUT-06	Diversion ditch (in-ditch or outlet)	60	**5.60**	**5.89**	**6.09**	6.60	7.60	7.71	8.20

Notes:
Values in bold are outside the B.C. or federal WQG pH range for the protection of freshwater aquatic life (6.5 to 9.0).
[1] SW-03 is estuarine and is compared to the B.C. and federal pH range for the protection of marine water aquatic life (7.0 to 8.7). Values in bold are outside the range.
[2] Data presented are the statistics of the compiled dataset (OUT-01, OUT-02, OUT-06, SW-05, SW-06) for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.

Downstream stations exhibit similar pH conditions, with values ranging from mildly acidic to circumneutral and generally consistent with those measured upstream. The frequency of pH measurements below the WQG lower limit for pH at downstream stations (5% to 57%) is comparable to that observed at upstream stations (18% to 100%), indicating pH at downstream stations is not influenced by the Project site.

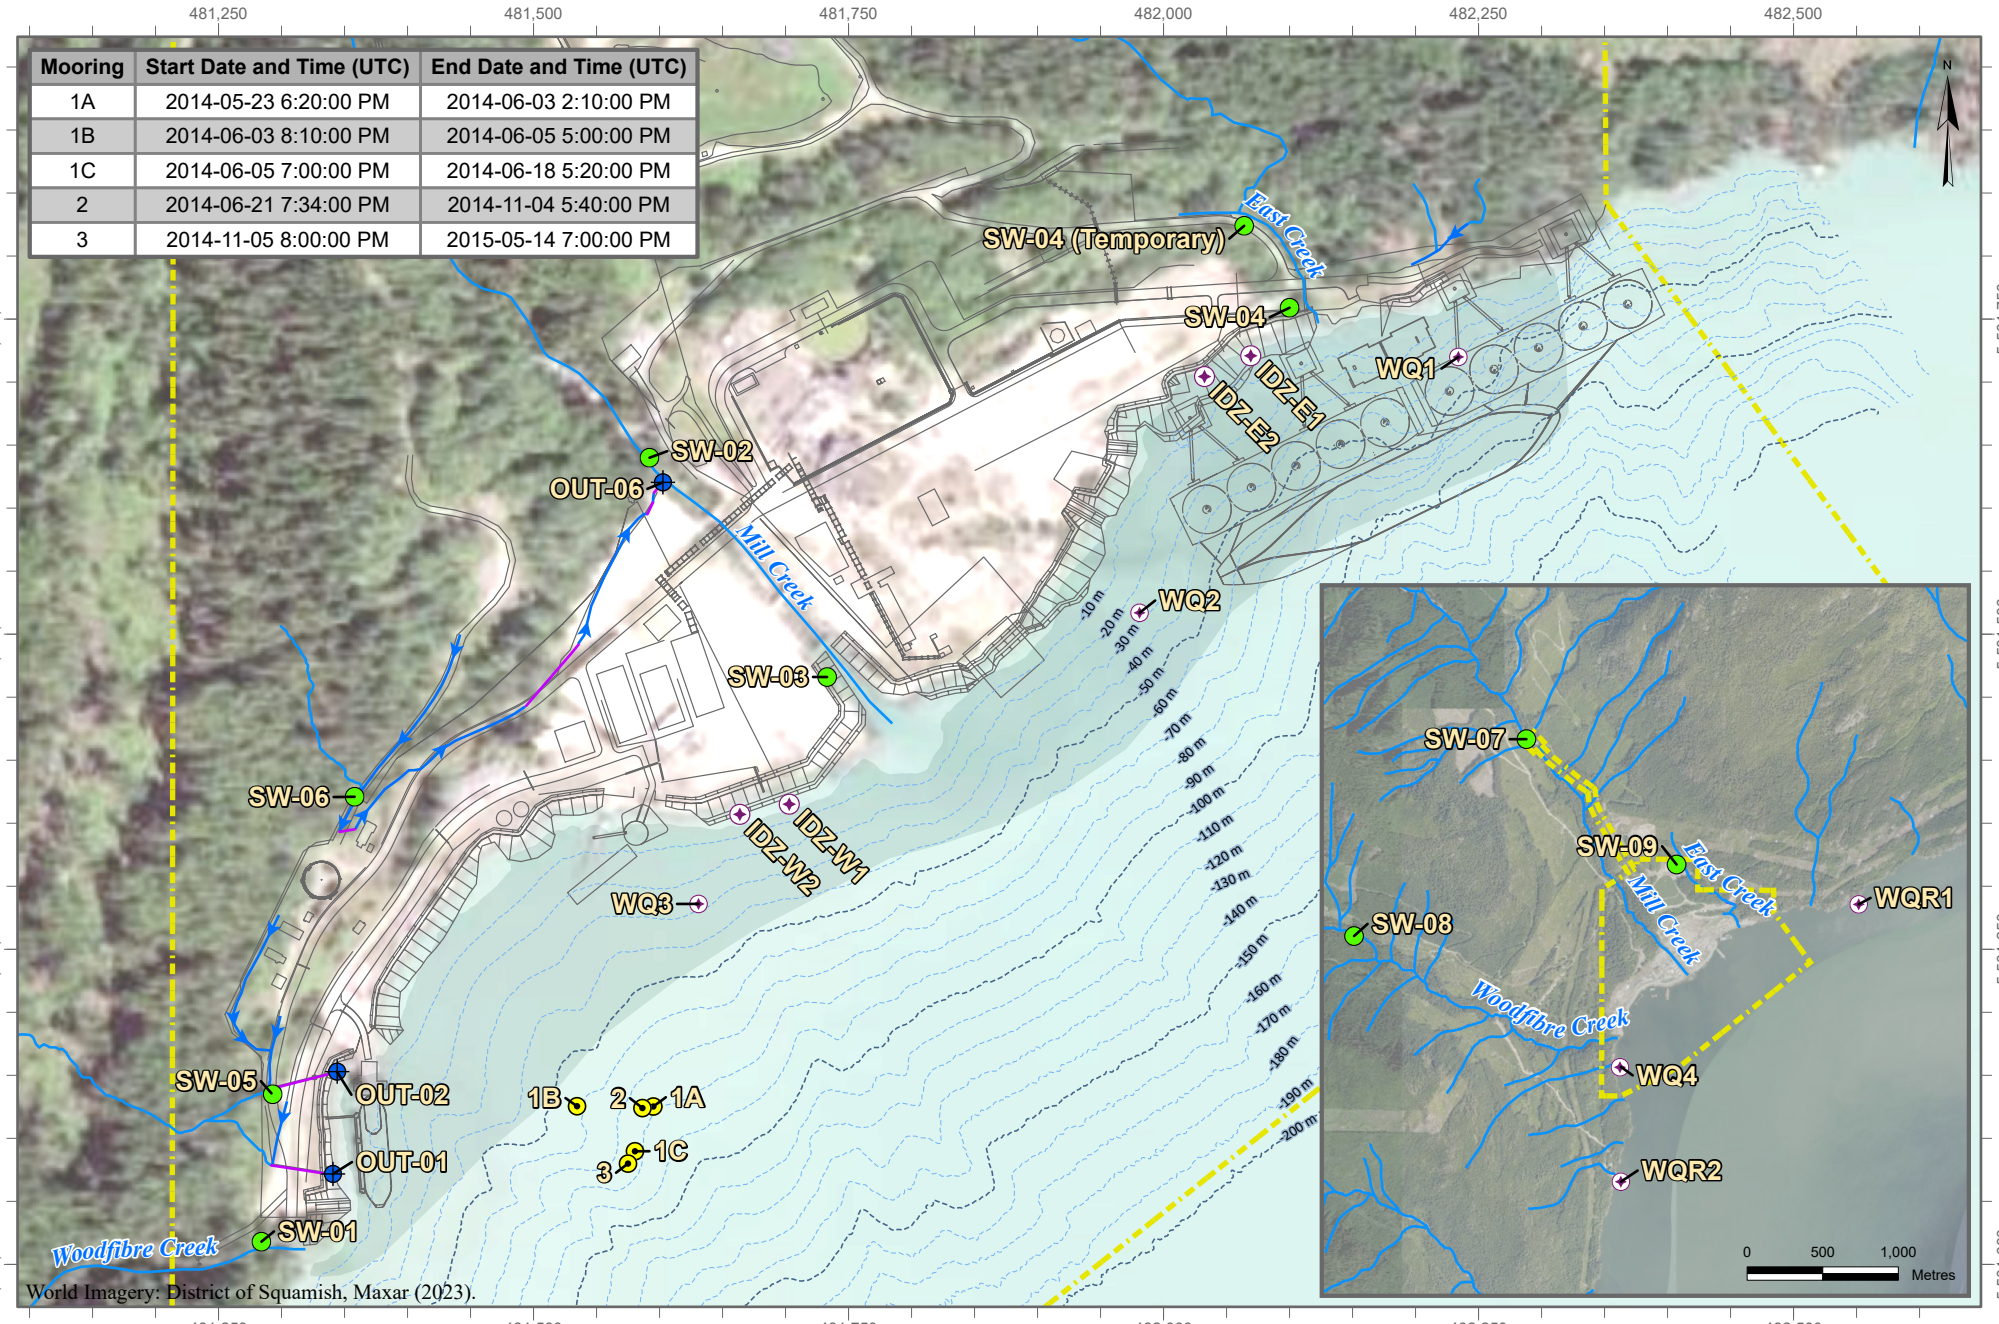
3.6.3.2 Comparison to Water Quality Guidelines

All surface water monitoring samples are evaluated by comparison with WQG for the protection of freshwater aquatic life (FWAL) with the exception of samples from lower

Mill Creek (SW-03). Lower Mill Creek is estuarine water due to marine water influence (as described in Section 3.5.1), and is therefore compared to Federal and B.C. WQG for the protection of MWAL. Results below detection limits are screened using the detection limit value. A statistical summary of water quality results for key parameters is provided for Woodfibre Creek (Table 3-16), upper Mill Creek (Table 3-17), lower Mill Creek (Table 3-18) and East Creek (Table 3-19). Water quality results for background stations is provided for Mill Creek (Table 3-20), Woodfibre Creek (Table 3-21) and East Creek (Table 3-22). Non-contact water quality collected from diversion ditches is summarized in Table 3-23.

The total aluminum (Al) concentration in all creeks is variable throughout the monitoring period, with lower concentrations typically measured during summer months and highest concentrations typically measured during the spring and autumn months. Frequent exceedances of the total Al WQG are noted at both Project site monitoring stations (SW-01, SW-02 and SW-04) and background monitoring stations upstream of the Project site (SW-08, SW-07 and SW-09) on Woodfibre Creek, Mill Creek and East Creek. Although the concentration of total Al was higher in samples from East Creek (SW-04) relative to other stations, the frequency of WQG exceedances was lower due to the dependence of the WQG on the concentration of DOC, total hardness and pH which are present in higher concentrations at SW-04.

Frequent exceedances of the dissolved Cu WQG (chronic and acute) were measured at all surface water monitoring stations on Woodfibre Creek, Mill Creek and East Creek. The frequency of dissolved Cu exceedances is similar between Woodfibre Creek, upper Mill Creek and East Creek, however, dissolved Cu concentrations are typically higher in East Creek. Although the dissolved Cu concentrations at the East Creek background monitoring station SW-09 are lower than those measured at SW-04, they are elevated relative to the background stations outside of the Project site on Woodfibre and Mill Creek suggesting dissolved Cu concentrations in East Creek are naturally higher than in the other Creeks.



Infrequent exceedances of total methylmercury and dissolved Zn WQGs were measured at Project site monitoring stations on Woodfibre Creek, upper Mill Creek and East Creek. Exceedances of these metals occur at a similar frequency in the upstream Mill Creek station (SW-07); however, there were no exceedances for total methylmercury or dissolved Zn measured at upstream Woodfibre Creek (SW-08) or East Creek (SW-09). The concentration of total methylmercury and dissolved Zn was generally higher in samples from the downstream East Creek monitoring station (SW-04) relative to the upstream station SW-09, as well as Woodfibre Creek and upper Mill Creek upstream and downstream stations.

Overall, the concentration of most metals (*e.g.*, Cd, Cu, Fe, Mo, Ni, Fe, Sb, strontium [Sr], uranium [U], Zn) were higher in samples from downstream East Creek (SW-04) relative to both upstream East Creek and Woodfibre and Mill Creek.

Trace concentrations of some PAHs and VOCs were infrequently detected in samples from Project site monitoring stations on Woodfibre Creek, upper Mill Creek and East Creek at concentrations below applicable WQG with the exception of one sample from SW-02 (Table 3-16 through Table 3-22). Although WQG for anthracene, benz(a)anthracene, benzo(a)pyrene and fluoranthene were exceeded in one sample collected from SW-02 on April 22, 2021, all other samples collected from this station during the monitoring period were below the limits of detection for these parameters. No PAHs or VOCs were detected in samples from background stations outside of the Project site (*i.e.*, SW-07, SW-08 or SW-09). PCDD/Fs were detected in some monitoring samples from the Project site stations (11% to 14% of samples) and at background stations (16% to 28% of samples). Although the lower bound PCDD/F toxic equivalent (TEQ) values are generally higher for downstream Woodfibre Creek and Mill Creek stations (SW-01, SW-02) relative to background stations (SW-07, SW-08), the upper bound PCDD/F TEQ values are comparable between Project site and background monitoring stations at all creeks. No heavy extractable petroleum hydrocarbons (HEPH) or light extractable petroleum hydrocarbons (LEPH) were detected in surface water samples from Woodfibre Creek, Mill Creek or East Creek during the monitoring period.

Exceedances of Federal and B.C. WQG for the protection of MWAL were noted in monitoring samples from lower Mill Creek station SW-03 for pH, dissolved oxygen, total metals (*i.e.*, boron [B], Cu, Cr) and benzo(a)pyrene. Although the field pH was frequently below the lower limit of the WQG range (7.0 – 8.7) at SW-03 during the monitoring period, the median pH was comparable to that measured at the upstream Mill Creek stations (*i.e.*, SW-02 and SW-07). Total B, Cu and Cr concentrations, while infrequently above WQG, were typically higher in samples from lower Mill Creek relative to upper Mill Creek stations. The high concentrations of total B and Cu are likely reflective of the marine influence noted at SW-03. Organic contaminants (hydrocarbons, PAHs, VOCs, PCDD/Fs) were also infrequently detected in samples from lower Mill Creek station, however, only benzo(a)pyrene was detected at concentrations above WQG in two monitoring samples.

Non-contact water from the slopes above and outside the Project construction area is intercepted by diversion ditches and conveyed to Howe Sound or Mill Creek. To evaluate non-contact water quality, samples from monitoring stations OUT-01, OUT-02, OUT-03, SW-05 and SW-06 are compared to WQG for the protection of FWAL. The pH of non-contact water quality is frequently below the lower limit of the WQG range (pH 6.5 to 9.0). Frequent exceedances of total Al and dissolved Cu, occasional exceedances of dissolved Zn and infrequent exceedances of total methylmercury are observed in non-contact water. Trace concentrations of organic contaminants are infrequently detected in non-contact water samples, at concentrations less than WQG.

Notes:
Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.
B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.
For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.
Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment.
[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.
[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.
[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-17:
Upper Mill Creek (SW-02) Surface Water Quality Summary (Upstream of Estuary)

Notes:
Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.
B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.
For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.
Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment.
[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.
[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.
[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Notes:

Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.

B.C. WQG MWAL: British Columbia water quality guideline for the protection of marine and estuarine aquatic life; CWQG MWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine and estuarine aquatic life.

Non-detect results are screened using the detection limit value.

Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.

Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.

[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment.

[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document.

[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.

[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.

[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.

[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.

[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-19:
East Creek (SW-04) Surface Water Quality Summary

Parameter	Unit	Provincial Guideline (BC WQG FWAL)		Federal Guideline (CWQG FWAL)		East Creek (SW-04)						
		Long-term	Short-term	Long-term	Short-term	Number of Samples	Number of Detectable Values	Min	P10	Median	P90	Max

Notes:
Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.
B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.
For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.
Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment.
[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.
[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.
[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-20:
Upstream Mill Creek (SW-07) Surface Water Quality

Parameter	Unit	Provincial Guideline (BC WQG FWAL)		Federal Guideline (CWQG FWAL)		Upstream Mill Creek (SW-07)

Notes:

Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.

B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.

For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.

Non-detect results are screened using the detection limit value.

Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.

Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.

[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Station SW-07 is a background station that does not receive discharge, therefore no WQG is established.

[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.

[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.

[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.

[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.

[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-21:
Upstream Woodfibre Creek (SW-08) Surface Water Quality

Parameter	Unit	Provincial Guideline (BC WQG FWAL)		Federal Guideline (CWQG FWAL)		Upstream Woodfibre Creek (SW-08)

Notes:

Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.

B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.

For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.

Non-detect results are screened using the detection limit value.

Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.

Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.

[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Station SW-08 is a background station that does not receive discharge, therefore no WQG is established.

[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.

[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.

[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.

[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.

[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-22:
Upstream East Creek (SW-09) Surface Water Quality

Parameter	Unit	Provincial Guideline (BC WQG FWAL)		Federal Guideline (CWQG FWAL)		Upstream East Creek (SW-09)

Notes:

Data presented is the statistics of the compiled dataset for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.

B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.

For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.

Non-detect results are screened using the detection limit value.

Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.

Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.

[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Station SW-09 is a background station that does not receive discharge, therefore no WQG is established.

[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.

[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.

[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.

[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.

[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-23:
Non-Contact Water Quality from Diversion Ditches (OUT-01, OUT-02 OUT-06, SW-05 and SW-06)

Parameter	Unit	Provincial Guideline (BC WQG FWAL)		Federal Guideline (CWQG FWAL)		Non-Contact Water Diversion Ditch Outlets (OUT-01, OUT-02, OUT-06, SW-05, SW-06)

Notes:

Data presented is the statistics of the compiled dataset (OUT-01, OUT-02, OUT-06, SW-05, SW-06) for the August 2018 to May 2025 monitoring period (Appendix 3.6-1); duplicate samples are not included.

B.C. WQG FWAL: British Columbia water quality guideline for the protection of freshwater aquatic life; CWQG FWAL: Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of freshwater aquatic life.

For parameters with variable water quality guidelines, values presented are based on median sample toxicity modifying factors (*e.g.*, dissolved organic carbon (DOC), pH, temperature) calculated from the Aug 2018 to May 2025 dataset.

Non-detect results are screened using the detection limit value.

Values shaded in light grey exceed the applicable long-term B.C. WQG FWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG FWAL.

Bolded values exceed the applicable long-term CWQG FWAL and underlined values exceed the applicable short-term CWQG FWAL.

[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Non-contact water stations (OUT-01, OUT-02, OUT-06, SW-05, SW-06) do not receive discharge, therefore no WQG is established.

[2] The WQG for hexavalent chromium (Cr(IV)) is conservatively applied to total chromium results.

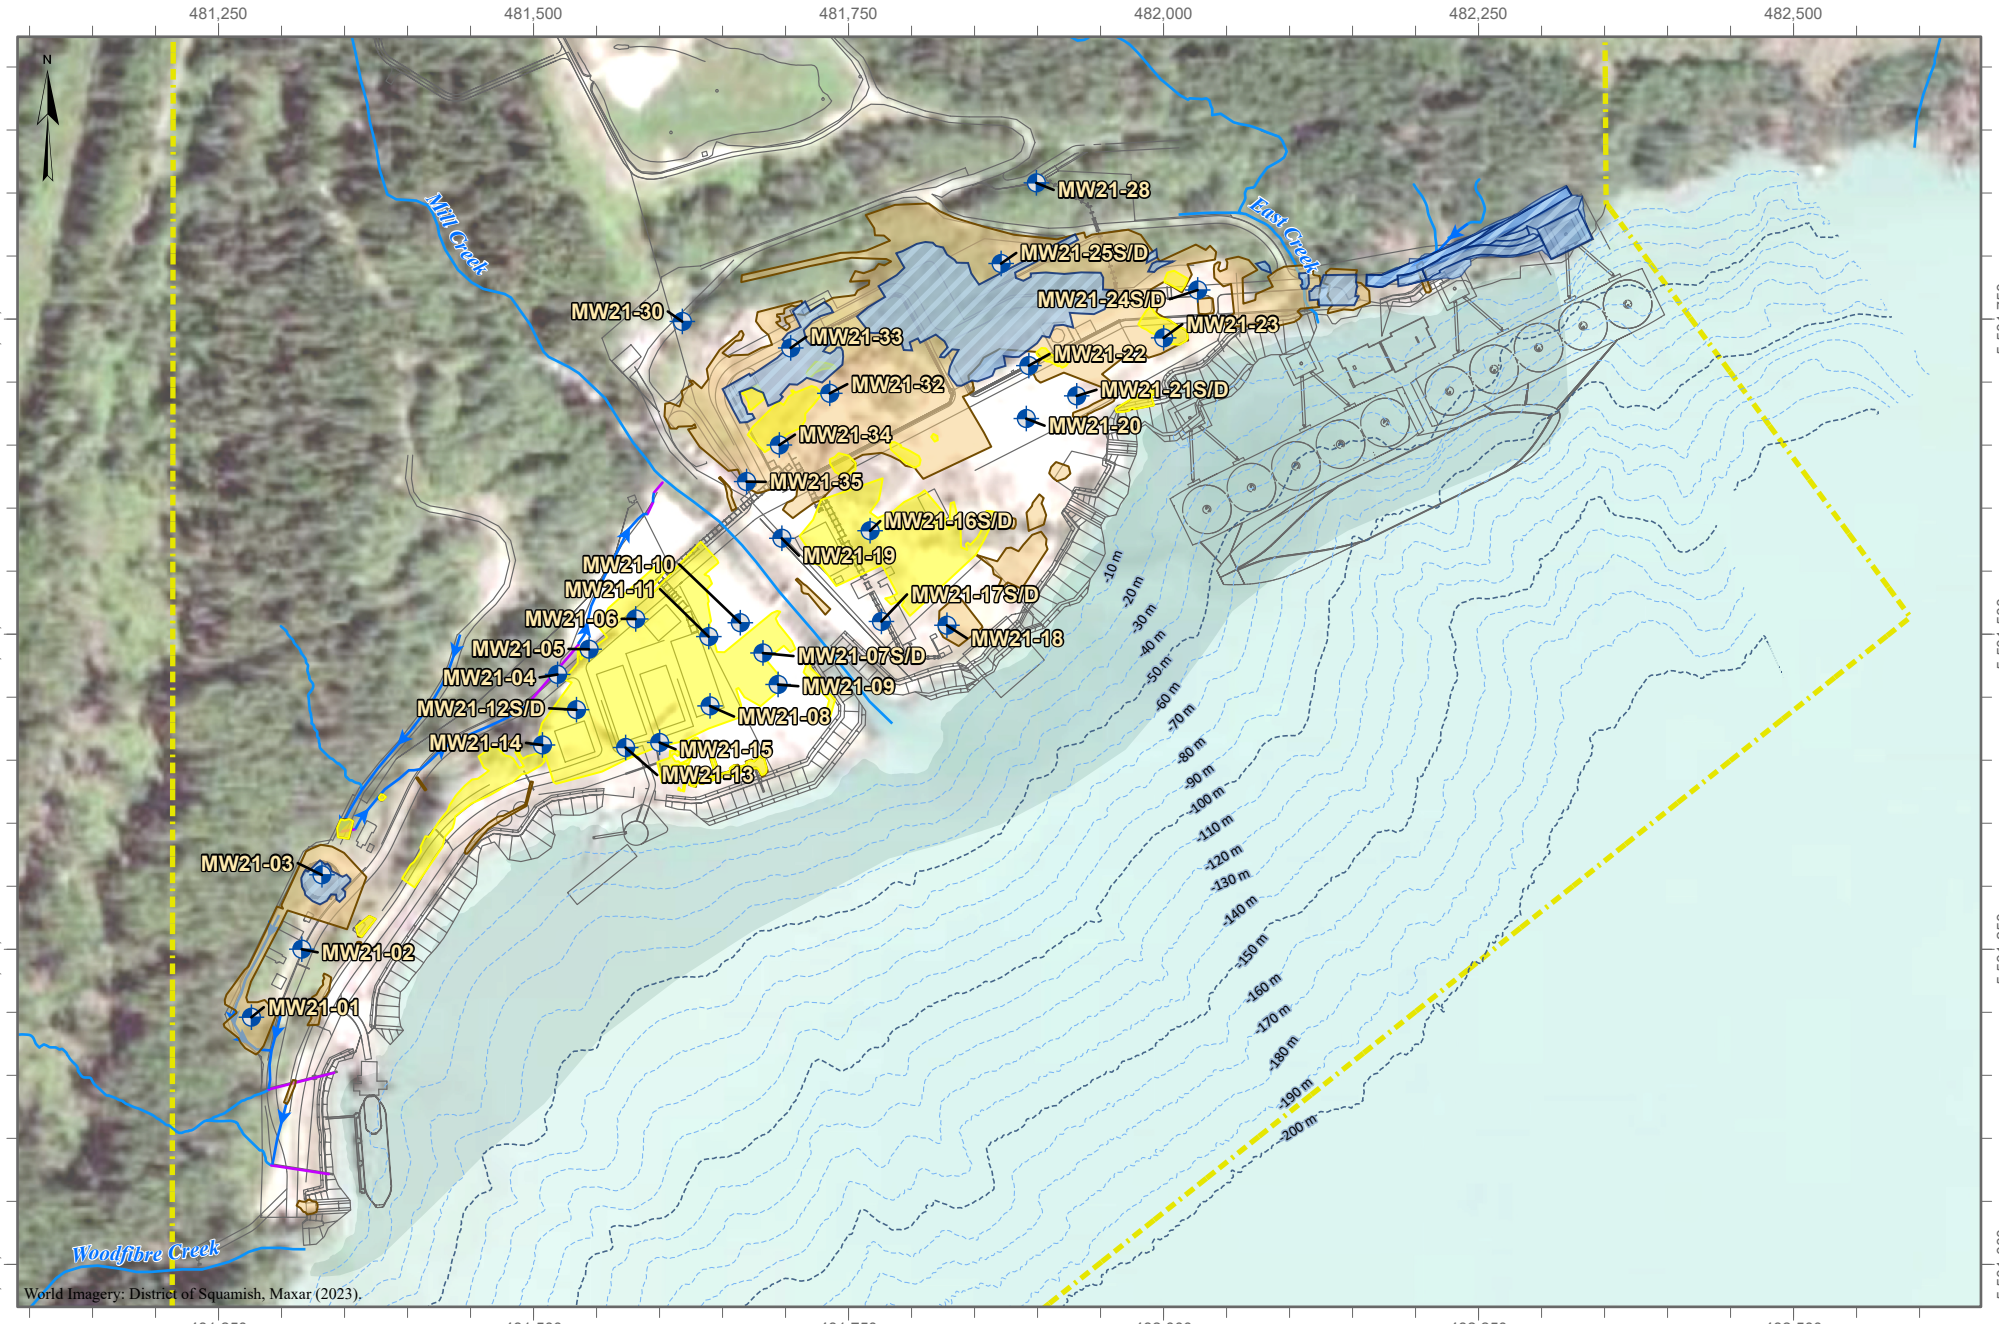
[3] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.

[4] The B.C. WQG-FWAL for acridine, anthracene, benz(a)anthracene, fluoranthene and pyrene applied are for photo-toxic freshwater environments.

[5] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.

[6] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

3.7 Hydrogeology



Hydrogeological conditions in the Project site were characterized prior to construction to establish baseline groundwater quality and groundwater quantity to inform the potential for groundwater inflows into open excavations, and to evaluate the potential for negative groundwater interaction associated with open excavations (Stantec, 2022a). The results of the monitoring program were presented in the technical assessment report for the construction WDA (Lorax, 2023) that supported the application for WDA Effluent Permit PE-111578. For completeness of this TAR, a brief description of the pre-construction (Stantec, 2022a) monitoring program is presented below.

The baseline hydrogeochemical assessment (Stantec, 2022a), included a physical and chemical hydrogeology program with the following components:

1) borehole advancement and subsurface soil characterization at 35 distinct locations and the installation of 38 monitoring wells across the development area (Figure 3-14);
2) quantification of hydraulic properties of subsurface materials through slug testing of 12 monitoring wells and constant rate pumping tests of six (6) wells; and,
3) completion of four (4) groundwater monitoring and sampling events to characterize baseline conditions, groundwater impacts and inform groundwater management during Construction.

Monitoring well installation and groundwater sampling were conducted in accordance with the B.C. Ministry of Environment and Climate Change Strategy (now known as B.C. Ministry of Environment and Parks) field sampling manual, and technical guidance on contaminated sites (Stantec, 2022a).

The assessment of physical hydrogeology included manual and automated groundwater level measurements and hydraulic testing (Stantec, 2022a). Manual water level measurements were collected during four monitoring events in February/March 2021, June 2021, November/December 2021, and March 2022. Groundwater was generally close to the ground surface (above ground to approximately 7 m below ground) across the Project site, with elevations that ranged approximately 0 to 43 meters above sea level (masl).

LEGEND

- Monitoring Well
- Cut and Demo - Soil Improv Excavation
- Overburden Excavation
- Rock Blasting
- Site Linework (Reduced)
- Certified Project Area
- Watercourse
- Non-Contact Ditch
- Culvert / Outfall
- Bathymetry Contour (Major: 50m)
- Bathymetry Contour (Minor: 10m)

Note: Overburden excavation and rock blasting areas are shown through January 2025.

P:\@202506\Woodfibre\Drafting Figures\APRX\TAR - Operations Phase - Groundwater\TAR - Operations Phase - Groundwater\TAR - Operations Phase - Groundwater.aprx Figure 3-14 Pre-Construction Monitoring Wells

Pressure transducers were deployed in 12 monitoring wells in 2021 to collect hourly water level, temperature, and specific conductance measurements. Groundwater hydrographs generated from pressure transducer data showed limited to no seasonal variation through the monitoring record; however, a direct relationship between precipitation events and groundwater elevation, indicative of groundwater recharge was observed in the hydrographs across most of the Project site (Stantec, 2022a). Tidal influence on groundwater levels was also evaluated using the pressure transducer data, whereby time series groundwater levels and specific conductivity showed that wells near the seashore were tidally influenced, with decreasing influence with distance from the shore. Groundwater wells in the upslope areas showed no sign of tidal influence, which suggested that these wells were disconnected from the water table in the lower deltaic deposits. Further details on groundwater level responses across the Project site are provided in Stantec (2022a).

Hydraulic testing (slug tests, constant head pumping tests) was completed in 2021 to evaluate the hydraulic properties of subsurface materials at the Project site. Slug tests and pumping tests were completed in wells screened in materials ranging mainly from silt to gravel. Hydraulic conductivity estimates were obtained from the slug tests and pumping test, with storage coefficients estimated from the pumping tests.

Groundwater quality samples were collected approximately quarterly between February 2021 and March 2022 from up to 37 monitoring wells (Stantec, 2022a). Low flow purging and sampling methods were employed in general agreement with procedures outlined in US EPA (2017). Groundwater quality samples were analyzed for BTEX, VPH, LEPH, HEPH, PAH, total metals, dissolved metals, and/or general chemistry. In March and/or June 2021, PCDD/Fs were also tested in groundwater sampled from three wells in the vicinity of the historic pulp mill weak liquor tanks and diffuser infrastructure where hydrocarbon staining, odour, and an oily black sheen and/or potential black liquor were observed on sampling equipment and/or soils intersected by these wells. A total of 140 groundwater samples, including 14 field duplicate samples, were collected.

Additional groundwater samples were collected during pumping tests (three samples per well) completed in January and February 2021. Pumping tests were completed at six wells installed within the vicinity of general excavation areas. The purpose of sampling during the pumping tests was to characterize groundwater quality and determine if groundwater chemistry changed during pumping which could indicate mobilization of unknown contaminants due to pumping/dewatering (Stantec, 2022a).

Groundwater quality results from the quarterly monitoring events are tabulated and compared to B.C. CSR Generic Numerical Water Quality Standards for the protection of

FWAL and MWAL in Appendix 3.7-1. A statistical summary of the groundwater quality results for key parameters across the Project site is provided in Table 3-24. Results below detection limits are screened using the detection limit value. Parameters reported above the standards for the protection of FWAL include chloride, nitrite (as N), LEPH, pyrene, dissolved copper and dissolved chromium in one to seven groundwater samples. Nitrite (as N), LEPH, pyrene, dissolved copper and dissolved chromium also exceed the standards for the protection of MWAL in one to five samples. The statistical summary shows that 90th percentile values for all analytical parameters are below the standards for the protection of FWAL and MWAL. Further details regarding groundwater quality results across the Project site are provided in Stantec (2022a).

Baseline monitoring wells were situated within or close to soil improvement, overburden excavation, and bedrock blasting areas (Figure 3-14). The monitoring well network is reported by WLNG to no longer exist because of civil construction activities at the Project site, with groundwater monitoring ceasing in March 2022.

The B.C. Water Resource Atlas, a mapping application that displays water-related data, was searched on December 16, 2025. According to the B.C. Water Resource Atlas, there are no registered aquifers and no registered wells within or immediately downgradient of the Project site. The closest registered aquifers are located at a distance greater than six kilometers from the Project site (*i.e.*, at Shannon Falls and in Squamish, across and at the end of Howe Sound, respectively). The closest registered water supply well is situated approximately three kilometers across Howe Sound, near Murrin Provincial Park. Groundwater uses downgradient and within one kilometer of the Project site include marine and estuarine aquatic life.

Table 3-24:
Project Site Groundwater Water Quality Summary (February 2021 to March 2022)

Notes:
Shaded values exceed the British Columbia (BC) Contaminated Site Regulation (CSR) Generic Numerical Water Quality Standards (Schedule 3.2) to protect freshwater aquatic life.
Bolded values exceed the British Columbia (BC) Contaminated Site Regulation (CSR) Generic Numerical Water Quality Standards (Schedule 3.2) to protect marine and estuarine aquatic life.
Values preceded by < indicate a detection limit. Detection limits were included in statistics calculations using their full value.
[1] BC CSR standard is calculated based on mean water hardness calculated from 'dissolved' mineral content – Hardness, mg equivalent CaCO3/L. Hardness is for the aquatic receiving environment.
[2] The BC CSR standard for nitrite is calculated based on chloride concentration.
[3] The BC CSR standard for hexavalent chromium (Cr(IV)) is conservatively applied to dissolved chromium.
[4] BC CSR standard is applicable at all sites, irrespective of water use.
[5] EPH (10-19) – Extractable Petroleum Hydrocarbons (nC10-nC19) in water includes all the extractable petroleum hydrocarbons with a carbon range from 10 to 19 obtained by the approved methods, where approved methods are specified by a director's protocol.
[6] LEPH – Light Extractable Petroleum Hydrocarbons in water, is the sum of extractable petroleum hydrocarbons with a carbon range from 10 to 19 obtained by the approved methods minus the sum of naphthalene and phenanthrene, where approved methods are specified by a director's protocol.

3.8 Marine Sediments

This section describes marine sediment conditions within the Project boundaries to the end of August 2025. The Project boundary extends up to 460 m from the shoreline into the marine environment, as shown on Figure 3-15. Marine sediment quality within the Project boundaries has been impacted by historic industrial activities at the Woodfibre site that include the placement of fill in the foreshore environment, influence from woodchip piles located on the foreshore, and discharge of pulp mill effluent to Howe Sound (Keystone, 2014a). Marine sediments adjacent to the shoreline within the Project boundaries are managed under the B.C. CSR. Sediments contaminated with tributyltin or covered with woodchips were remediated in 2013 by dredging. Following the remediation, the residual concentrations of parameters of concern (*i.e.,* Cu, Pb, and PAHs) in sediments were determined to be low risk to ecological receptors (Keystone; 2014c and 2014d). The B.C. Ministry of Environment issued a CofC for the water lot (*i.e.*, marine sediments) portion of the Project site in December 2014 (refer to Section 1.2).

Water depth in the Project area ranges from zero at the shoreline to greater than 200 mas shown in Figure 3-15. Marine sediments in the Project area are predominantly fine-grained, composed mainly of clay, silt, and sand. This particle size distribution is consistent with the broad regional sediment facies (sandy silt, and silt) described by Syvitski and MacDonald (1981). Coarser-grained sediments are concentrated near west of Mill Creek and along the shoreline in the northeast portion of the marine area. Samples with very high (> 60 %) sand and gravel content are clustered around previously dredged areas.

3.8.1 Marine Sediment Monitoring Programs

This section provides an overview of marine sediment sampling programs conducted from 2006 to 2025. A total of 152 samples collected from non-dredged areas are included in the sediment dataset. The monitoring programs and parameters tested are summarized in Table 3-25 and Table 3-26, respectively.

Table 3-25:
Summary of Marine Sampling Programs Included in the Sediment Dataset

Project Stage	Sampling Year	No. of Site Samples	No. of Reference Samples	Sampling Program(s)	Sampling Method
CSR Investigation	2006	36	3	Preliminary Site Investigation (PSI) Stage 2 / Detailed Site Investigation (DSI) (Keystone)	Grab and/or core sampler
	2007	12	0		Grab and/or core sampler
	2013	15	3	Supplementary Site Investigation (SSI) (Keystone)	Grab sampler
EA Application to Construction	2014	8	2	EA Baseline (Golder)	Grab sampler
	2019	11	0	Post-docks/piles removal sampling (Keystone)	Hand sampler
	2021	6	4	Pre-Construction Baseline (Keystone)	Grab sampler
	2022	7	0	Geotechnical sampling (Stantec)	Core sampler
	2023	13	0	Initial Dilution Zone (IDZ) Baseline (Keystone)	Grab sampler
Construction Monitoring	2024	10	2	IDZ Monitoring (Roe); Floatel monitoring (Keystone)	Grab sampler
	2025	34	4	IDZ monitoring (Roe); Floatel & site-wide monitoring (Keystone)	Grab Sampler

Notes:
Duplicate and triplicate samples were not included in the Number of Samples count.
Reference samples were collected outside the Project site boundary.
Hand samplers = samples collected by divers using scoops, spoons, or shovels; Grab sampler = Ponar and Van Veen samplers deployed on poles or lines from boats; Core samplers = gravity corers, poston corers, box corers, and vibracorers deployed from boats or barges

Table 3-26:
Parameters Analysed in Marine Sediments

[3] Sample count based on PCDD/F, lower bound TEQ.
[4] Sample count based on aroclor 1254.

3.8.2 Sediment Quality Results

Sediment quality is represented by marine sediment data from 152 samples collected from 2006 to 2025 (Table 3-26). Samples collected from areas that were subsequently dredged, or were collected from cores below 0.5 m depth are excluded from the dataset. The 0.5 m depth threshold reflects the maximum extent of bioturbation in marine sediments and aligns with the typical penetration depth of grab samplers (*e.g.*, Ponar, Van Veen). Surface grab and diver-collected hand samples are assumed to have a depth of 0 m unless otherwise specified. Tabulated sample results are presented in Appendix 3.8-1.

The marine sediment results are screened against the B.C. CSR Schedule 3.4 marine sediment standard for sensitive use, the B.C. Working Sediment Quality Guideline for the Protection of Benthic Aquatic Life in marine environments, and the CCME Sediment Quality Guidelines for the Protection of Marine Aquatic Life (interim sediment quality guideline and probable effects levels) as listed in Table 3-27. Summary statistics for

parameters with applicable guidelines are presented in Table 3-28. Where duplicate or triplicate samples are available, results are averaged for inclusion in the summary statistics. Marine sediment duplicates and triplicates show some variability, which reflects the heterogeneity of the sampling medium.

Marine sediment sampling locations are illustrated relative to key Project infrastructure in Figure 3-15. Sample locations are colour-coded according to the proportion of parameters that exceeded a guideline. This scheme is selected to compensate for varied analytical parameters across sampling programs (see Table 3-16). Sampling locations where more than 75% of measured parameters exceed the lowest applicable guideline are generally clustered in proximity to the shoreline.

Marine sediments in the Project area have elevated concentrations of metals, PAHs, PCDD/Fs, and PCBs with respect to reference standards and guidelines. The sediments exhibit strong heterogeneity with respect to all parameters, represented by the minimum and maximum concentrations (Table 3-28). Maximum values exceed one or more applicable guidelines for the majority of parameters. PAH and PCDD/F TEQ median values frequently exceed applicable guidelines.

Across the Project area, marine sediment quality is heterogeneous; samples collected south of Woodfibre Creek exhibit a lower proportion of guideline exceedances compared to samples collected between Woodfibre Creek and Mill Creek. Elevated concentrations of metals, PAHs, and PCDD/F TEQs are indicated at stations near the shoreline compared to those in deeper waters.

The sediment dataset provides broad spatial resolution of sediment data within the Project boundaries, including deep-water samples collected in 2006 and a high density of samples in the vicinity of Project infrastructure. There are no discernible trends that distinguish construction monitoring data (2024 to 2025) from pre-construction monitoring results.

3.9 Marine Water Quality

The Howe Sound marine water quality is influenced by freshwater inputs from Squamish River. Freshwater is usually more buoyant than seawater, and therefore tends to form a buoyant surface layer that is a mixture of freshwater and marine water. The surface layer is usually isolated from the more saline deeper water at the Project site. Therefore, marine water quality is usually monitored at several depths to obtain representative samples from the surface layer and deeper waters.

Marine water quality within the Project boundaries and at nearby reference was intermittently monitored in 2006, and 2013 to 2015, and has been routinely monitored since May 2020. Prior to 2020, monitoring was conducted at a variety of locations and depths; however, since May 2020, monitoring has been conducted at the same stations and at two depths, with the addition of third depth in December 2023. The water quality results for the 2006, and 2013 to 2015 samples were comparable to samples collected since 2020 and the results were included in the technical assessment report for the construction WDA (Lorax, 2023) that supported the application for WDA Effluent Permit PE-111578. Approximately five years of monitoring has been conducted at the stations established in 2020, and the monitoring dataset is considered to be a comprehensive representation of water quality prior to operation of the Project, therefore only these results are summarized in this section. Monitoring is ongoing; however, results are presented for data that were available (May 2020 through May 2025) at the time the TAR preparation commenced.

Water quality data are presented for samples collected from the monitoring stations that were established in May 2020 (refer to Section 3.9.1). Marine water quality samples collected during construction to monitor the influence of in-marine works or construction effluent discharge have been excluded from the data assessment presented in this section, because they may be construction influenced and are not considered to be representative of background marine water quality within the Project boundaries.

3.9.1 Monitoring Program Summary

A total of 1,653 marine water quality monitoring samples were collected at a monthly and occasionally weekly frequency from May 2020 to May 2025 from four monitoring stations within the Project boundaries (WQ1, WQ2, WQ3 and WQ4) and at two reference stations established 500 m north (WQR1) and south (WQR2) of the northern and southern boundaries, respectively. The locations of the marine water monitoring stations are shown in Figure 3-13 and a description of the monitoring stations is provided in Table 3-29. A Van Dorn sampler was used to collect water samples from 2 m below the water surface

and 2 m above the seafloor, and since December 2023 at 0.5 m below the water surface. The marine water quality sampling programs are summarized below:

- Monthly sampling commenced May 2020 to monitor pre-construction conditions. Monthly monitoring has continued through the construction period.
- Weekly and monthly monitoring in accordance construction WDA Effluent Permit PE-111578 has been undertaken since April 2024. The monitoring program includes reference stations WQR1 and WQR1. Therefore, the data for these stations are included in the data assessment.

Table 3-29:
Marine Water Quality Monitoring Stations

Station	Latitude	Longitude	Description
WQ1	49.667750	-123.246200	East of East Creek and the historic chip unloading and barge berthing facilities, where the FSTs will be permanently moored.
WQ2	49.665917	-123.249700	Northeast of Mill Creek mouth and the historic timber wharf that has been removed, and between the future FSTs and material offloading facilities within the Project area.
WQ3	49.663833	-123.254533	Southwest of Mill Creek mouth, located within the Project area.
WQ4	49.659633	-123.258633	Southwest of Woodfibre Creek mouth at the site of the floating worker accommodations (Floatel 1), located within the Project area.
WQR1	49.669367	-123.236800	Reference site located northeast of East Creek 500 m northeast of the Project boundary.
WQR2	49.652817	-123.258517	Reference site located south of Woodfibre Creek and 500 m south of the Project boundary.

Water quality testing included field measurements (*i.e.,* temperature, turbidity, conductivity, salinity, pH and dissolved oxygen) and analytical testing at accredited laboratories for physical parameters (pH, turbidity, TSS, TDS), general parameters (nutrients and anions), total and dissolved metals, speciated metals (methylmercury, hexavalent and trivalent chromium), hydrocarbons, PAHs, VOCs, PCDD/Fs and *Escherichia coli* (E. coli).

Analytical testing was completed at CALA accredited laboratories. For most of the tested parameters, analytical detection limits have either decreased or remained the same with the change in analytical testing laboratories; therefore, higher detection limits are observed during the pre-construction baseline marine water quality monitoring.

3.9.2 Quality Assurance and Quality Control

Field quality control included the collection of field blanks, trip blanks, and field duplicates. A total of 342 QA/QC samples comprised of 187 blank samples (110 field blanks and 77 travel blanks) and 155 duplicate samples were collected representing 21% of the 1,653 monitoring samples collected during the May 2020 to May 2025 period.

The blank sample evaluation indicates that 2.5% of all parameters tested in blank samples showed concentrations above the detection limit value and 1.3% of detectable parameters show concentrations greater than two times the detection limit value. Metal species that were detected in more than five blank samples at comparable levels to the monitoring dataset include total Zn and dissolved Cu; however, these instances occur in less than 5% of all blank samples and do not meaningfully alter the interpretation of the data. Select PAHs (benz(a)anthracene and benzo(a)pyrene) and VOCs (toluene and chloroform) additionally show similar to higher rates of detection and magnitude of concentrations in blank samples compared to the monitoring dataset. It is noted that a field blank sample collected in November 2023 shows a benzo(a)pyrene concentration seven times greater than the long-term WQG (0.00001 mg/L). It is inferred that contamination associated with sample collection or testing may have contributed to the elevated parameter concentrations observed in blank samples and may have also influenced the concentrations detected in in monitoring samples. Therefore, monitoring results for benzo(a)pyrene, benz(a)anthracene and toluene reflect higher uncertainty than other parameters in the dataset. The source of chloroform contamination in blanks samples was determined to be from deionized water supplied by the laboratory containing trace levels of chloroform that was used to fill the blank sample bottles; therefore, the interpretation of the monitoring data is not affected because deionized water is not added to environmental samples.

Relative percent difference (RPD) calculated for field duplicate pairs demonstrates sufficient reproducibility as less than 2% of all duplicate parameter pairs show RPDs greater than 20% and less than 1% of all duplicate parameter pairs show RPDs greater than 50%. Parameters which show multiple instances of RPDs greater than 50% include TSS and total Al, Cu, Fe, Ni, Se, and Zn. These anomalies may reflect spatial variability of suspended particulate material. Although a degree of environmental variability is observed in the monitoring results, the variability is not expected to meaningfully alter the interpretation of the data as more than 98% of duplicate parameter pairs are shown to be highly reproducible.

3.9.3 Marine Water Quality Results

Overall, the May 2020 to May 2025 marine water quality dataset is considered representative of background marine water quality prior to operation of the LNG facility.

A summary of water quality results for key parameters at Project area stations at 0.5 and 2 m below the surface and 2 m above the seafloor are provided in Table 3-30, Table 3-31 and Table 3-32, respectively. A summary of water quality for key parameters at marine reference stations at 0.5 and 2 m below the surface and 2 m above the seafloor are provided in Table 3-33, Table 3-34 and Table 3-35, respectively.

Monitoring data are tabulated in Appendix 3.9-1 and are screened against Federal and B.C. WQG for the protection of MWAL. Results below detection limits are screened using the detection limit value. Observations and conclusions from the May 2020 to May 2025 marine water quality monitoring are described below. For the purpose of this discussion, shallow water describes samples collected at 0.5 and 2 m below the surface and deep water refers to samples collected at 2 m above the seafloor.

The water quality results for the marine baseline dataset are consistent with the understanding of stratification of the water column in the northern basin of Howe Sound and further described in Section 3.10. Water column stratification in Howe Sound is highly influenced by seasonal inputs from the Squamish River. Periods of high freshwater inputs in spring and summer reduce salinity concentrations in a shallow surface layer that extends from the mouth of Squamish River southward in Howe Sound waters and influences the shallow marine water quality within the Project area and at the reference stations. Water clarity and sediment loading are also influenced by seasonal freshwater inputs to Howe Sound with generally higher turbidity and TSS observed in spring and summer in the surface layer relative to the underlying oceanic layer within and outside the project boundary. Low concentrations of dissolved oxygen in deep water samples are comparable at stations within Project boundaries and at reference monitoring stations, indicating that low dissolved oxygen at depth is a background condition of marine water in Howe Sound. Dissolved oxygen concentrations in shallow marine water samples are lowest in winter months when the freshwater inputs from the Squamish River are at annual lows. Shallow water pH measurements show slight seasonal variability with minimum values generally measured in the winter months at both Project area and reference monitoring stations. In contrast, the deep water pH results are relatively stable throughout the year.

Marine water quality was evaluated by comparison with the Federal and B.C. WQG for the protection of MWAL. The WQG for the protection of MWAL were met for most parameters over the May 2020 to May 2025 monitoring period. Occasional exceedances were observed in deep and shallow water monitoring locations for pH, fluoride, and total metals (*i.e.*, Cd, Cr, Cu, Hg, Ni, Pb, Se, V and Zn) and more frequently for dissolved oxygen and total B.

Field pH is infrequently outside the range of the WQG (pH 7.0 to 8.7), showing values slightly below the lower limit primarily in shallow water samples collected at reference stations and values slightly above the upper limit primarily in shallow water samples collected at stations within Project boundaries. The pH values below the lower limit of the WQG were generally observed in fall and winter months while values above the upper limit of the WQG were observed in spring and summer months, reflecting seasonal variability in shallow marine water quality. The lower pH values may be associated with a relatively stronger local influence of low pH freshwater from local creeks in the shallow marine waters, when the influence from Squamish River outflows are less pronounced.

Dissolved oxygen is below the lower limit of the WQG (≥8 mg/L) in some shallow water samples and most deep water samples collected from both the Project area and reference monitoring stations. Similarly, total B exceeds the WQG in all deep water samples and in many shallow water samples at comparable frequencies at all stations. Low concentrations of dissolved oxygen and elevated concentrations of total B are inversely related to freshwater inputs from the Squamish River and local creeks, and are indicative of influence from the deeper saline waters in the northern basin of Howe Sound.

Occasional exceedances of WQGs for fluoride and total Cd, Cr, Hg, Ni and Se occur at comparable frequencies between Project area and reference stations indicating occasional presence above WQGs in marine water is a background condition in Howe Sound. The occasional exceedances of WQGs for total Cd, Cr and Se occur at a higher frequency in deep water samples relative to shallow water samples indicating the influence may originate in the deeper waters of Howe Sound, rather than surface inputs.

Exceedances of the WQGs for total Pb and Zn, although infrequent, occur at a slightly higher frequency in deep water samples collected at Project area stations than at reference stations while the frequency of WQG exceedances are comparable in shallow water samples collected in the Project area and reference monitoring stations. Many of the total Zn results were reported as non-detectable, and for some non-detectable results the detection limit value was well above the lowest reported detection limit (Table 3-30 through Table 3-35, and Appendix 3.9-1). Excluding elevated non-detectable results from the dataset (Appendix 3.9-1), the concentrations of total Zn in in Howe Sound surface waters at the Project area stations range from <0.0030 to 0.0064 mg/L, and <0.0010 to 0.0174 mg/L (0.5 m and 2.0 below surface, respectively), and at reference stations the total Zn concentrations range from <0.0030 to 0.0086 mg/L, and 0.0015 to 0.102 mg/L (0.5 m and 2.0 below surface, respectively). For reference, the long-term BC WQG is 0.01 mg/L.

Occasional WQG exceedances of total Cu are comparable between Project area and reference monitoring stations; however, the frequency of total Cu exceedances is higher in

shallow water relative to deep water monitoring locations. A few of the total Cu results for the reference stations were reported as non-detectable with some detection limit values well above the lowest reported non-detectable value (Table 3-33 through Table 3-35, Appendix 3.9-1). Excluding non-detectable results with elevated detection limits from the dataset (Appendix 3.9-1), the concentration of total Cu at the reference stations ranges from <0.0005 to 0.0044 mg/L (0.5 m depth), <0.0005 to 0.00974 mg/L (2 m depth), and <0.0005 to 0.00442 mg/L (2 m above seafloor). For reference, the long-term BC WQG is 0.002 mg/L.

Total V was infrequently detected above the Federal WQG (0.005 mg/L). Inconsistent elevated detection limits (<0.010, <0.025 and <0.050 mg/L) above the Federal WQG were reported from April 2022 to September 2023 and in October 2024 and are attributed to an analytical interference in the test method used by the laboratory.

Organic contaminants (*i.e.*, LEPH, HEPH, PAHs, VOCs and PCDD/Fs) are generally not detected in monitoring samples (Table 3-30 through Table 3-35). LEPH and HEPH are not detected in any monitoring samples. However, PAHs and VOCs are detected in some monitoring samples (<1% and <0.05%, respectively) and confirm occasional presence in the marine water column. The PAH parameter, benzo(a)pyrene, is occasionally detected above the WQG in some shallow water and deep water samples at Project area and reference monitoring stations and indicate benzo(a)pyrene may be present at trace concentrations in the marine waters within and outside the Project boundary. However, monitoring results for benzo(a)pyrene have a relatively higher uncertainty based on the field quality control evaluation (Section 3.9.2). Naphthalene is detected in one shallow water sample from within the Project area above the WQGs. PCDD/Fs are detected in some monitoring samples (<15%) at comparable frequencies in Project area and reference monitoring stations and confirm occasional presence in the marine water column across the Project area boundary. The range of lower and upper bound PCDD/F TEQ values is comparable between all stations at all depths.

Overall, parameter concentrations observed at Project area stations since construction commenced are within concentration ranges observed during the pre-construction monitoring period (*i.e.*, May 2020 to October 2023) or within background ranges observed at marine reference stations (May 2020 to May 2025). Generally comparable water quality is observed in samples collected from Project area and the reference stations. Trends observed in marine water quality at all monitoring stations are attributed to seasonal effects and the stratification of the water column in the northern basin of Howe Sound.

Table 3-30:
Summary of Marine Water Quality Within the Project Area (Stations WQ1, WQ2, WQ3 and WQ4) at 0.5 m Below Surface

Parameter	Unit	Provincial Guideline (BC WQG MWAL)		Federal Guideline (CWQG MWAL)		CPA Stations - 0.5 m Below Surface

Notes:
Compiled dataset for the May 2020 to May 2025 monitoring period (Appendix 3.9-1). Statistics of monitoring dataset; duplicate samples not included.
B.C. WQG MWAL = British Columbia water quality guidelines for the protection of marine aquatic life.
CWQG MWAL = Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine aquatic life.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.
Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. The turbidity and TSS WQGs were not evaluated.
[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. The total ammonia nitrogen B.C. WQG was calculated based on median salinity, pH and temperature values for CPA stations collected at 0.5 m below surface.
[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.
[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-31:
Summary of Marine Water Quality Within the Project Area (Stations WQ1, WQ2, WQ3 and WQ4) at 2 m Below Surface

Parameter	Unit	Provincial Guideline (BC WQG MWAL)		Federal Guideline (CWQG MWAL)		CPA Stations - 2 m Below Surface						
		Long-term	Short-term	Long-term	Short-term	Number of Samples	Number of Detectable Values	Min	P10	Median	P90	Max

Notes:
Compiled dataset for the May 2020 to May 2025 monitoring period (Appendix 3.9-1). Statistics of monitoring dataset; duplicate samples not included.
B.C. WQG MWAL = British Columbia water quality guidelines for the protection of marine aquatic life.
CWQG MWAL = Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine aquatic life.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.
Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. The turbidity and TSS WQGs were not evaluated.
[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. The total ammonia nitrogen B.C. WQG was calculated based on median salinity, pH and temperature values for CPA stations collected at 2 m below surface.
[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.
[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-32:
Summary of Marine Water Quality Within the Project Area (Stations WQ1, WQ2, WQ3 and WQ4) at 2 m Above the Seafloor

Parameter	Unit	Provincial Guideline (BC WQG MWAL)		Federal Guideline (CWQG MWAL)		CPA Stations - 2 m Above Seafloor

Notes:
Compiled dataset for the May 2020 to May 2025 monitoring period (Appendix 3.9-1). Statistics of monitoring dataset; duplicate samples not included.
B.C. WQG MWAL = British Columbia water quality guidelines for the protection of marine aquatic life.
CWQG MWAL = Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine aquatic life.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.
Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. The turbidity and TSS WQGs were not evaluated.
[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. The total ammonia nitrogen B.C. WQG was calculated based on median salinity, pH and temperature values for CPA stations collected at 2 m above the seafloor.
[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.
[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-33:
Summary of Marine Water Quality at Reference Stations (WQR1 and WQR2) at 0.5 m Below Surface

Parameter	Unit	Provincial Guideline (BC WQG MWAL)		Federal Guideline (CWQG MWAL)		Reference Stations - 0.5 m Below Surface						
		Long-term	Short-term	Long-term	Short-term	Number of Samples	Number of Detectable Values	Min	P10	Median	P90	Max

Notes:
Compiled dataset for the May 2020 to May 2025 monitoring period (Appendix 3.9-1). Statistics of monitoring dataset; duplicate samples not included.
B.C. WQG MWAL = British Columbia water quality guidelines for the protection of marine aquatic life.
CWQG MWAL = Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine aquatic life.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.
Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Water quality from reference stations represents background conditions, therefore the turbidity and TSS WQGs were not evaluated. The salinity WQG was not evaluated.
[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. The total ammonia nitrogen B.C. WQG was calculated based on median salinity, pH and temperature values for marine water quality reference stations collected at 0.5 m below surface.
[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.
[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-34:
Summary of Marine Water Quality at Reference Stations (WQR1 and WQR2) at 2 m Below Surface

Parameter	Unit	Provincial Guideline (BC WQG MWAL)		Federal Guideline (CWQG MWAL)		Reference Stations - 2 m Below Surface						
		Long-term	Short-term	Long-term	Short-term	Number of Samples	Number of Detectable Values	Min	P10	Median	P90	Max

Notes:
Compiled dataset for the May 2020 to May 2025 monitoring period (Appendix 3.9-1). Statistics of monitoring dataset; duplicate samples not included.
B.C. WQG MWAL = British Columbia water quality guidelines for the protection of marine aquatic life.
CWQG MWAL = Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine aquatic life.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.
Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Water quality from reference stations represents background conditions, therefore the turbidity and TSS WQGs were not evaluated. The salinity WQG was not evaluated.
[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. The total ammonia nitrogen B.C. WQG was calculated based on median salinity, pH and temperature values for marine water quality reference stations collected at 2 m below surface.
[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.
[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

Table 3-35:
Summary of Marine Water Quality at Reference Stations (WQR1 and WQR2) at 2 m Above the Seafloor

Parameter	Unit	Provincial Guideline (BC WQG MWAL)		Federal Guideline (CWQG MWAL)		Reference Stations - 2 m Above Seafloor						
		Long-term	Short-term	Long-term	Short-term	Number of Samples	Number of Detectable Values	Min	P10	Median	P90	Max

Notes:
Compiled dataset for the May 2020 to May 2025 monitoring period (Appendix 3.9-1). Statistics of monitoring dataset; duplicate samples not included.
B.C. WQG MWAL = British Columbia water quality guidelines for the protection of marine aquatic life.
CWQG MWAL = Canadian (CCME) and Federal (ECCC) water quality guidelines for the protection of marine aquatic life.
Non-detect results are screened using the detection limit value.
Values shaded in light grey exceed the applicable long-term B.C. WQG MWAL and values shaded in dark grey exceed the applicable short-term B.C. WQG MWAL.
Bolded values exceed the applicable long-term CWQG MWAL and underlined values exceed the applicable short-term CWQG MWAL.
[1] Field turbidity and total suspended solids (TSS) B.C. WQGs are induced guidelines for change from background conditions arising from discharges to the aquatic environment. Water quality from reference stations represents background conditions, therefore the turbidity and TSS WQGs were not evaluated. The salinity WQG was not evaluated.
[2] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. The total ammonia nitrogen B.C. WQG was calculated based on median salinity, pH and temperature values for marine water quality reference stations collected at 2 m above the seafloor.
[3] The working B.C. WQG for trivalent antimony [Sb(III)] is 0.27 mg/L and is applied to total antimony results.
[4] The WQG for hexavalent chromium (Cr(IV)) is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the total methylmercury concentration and was derived assuming methylmercury was 0.5% of the total mercury concentration.
[6] Lower-bound PCDD/F TEQ = Lower-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration of zero for results reported as not detected.
[7] Upper-bound PCDD/F TEQ = Upper-bound polychlorinated dibenzo-*p*-dioxin (PCDD) and polychlorinated dibenzofuran (PCDF) toxic equivalent (TEQ). Calculated assuming a concentration equal to the detection limit for results reported as not detected.

3.10 Oceanography

The Project is located on the shores of Howe Sound, a coastal fjord located in the Strait of Georgia. The fjord extends 42 km south from the mouth of the Squamish River to Burrard Inlet (Figure 1-1). Howe Sound is separated into two basins by a shallow underwater sill which crests at a depth of approximately 70 m below the surface. The sill was formed from a glacial moraine which extends from Defense Island to Porteau, approximately 11 km southwest of the Project site as indicated in Figure 3-16. North of this sill is the northern basin of Howe Sound which has a maximum depth of 285 m and is where the Project site is located (BCELUS, 1980; Golder, 2014).

The northern basin of Howe Sound is density stratified into three layers: a surface layer (between 0 and 10 m) that is influenced by surface processes, such as riverine runoff, wind, solar radiation, an intermediate layer (10 m – 70 m depth) that exchanges with the southern portion of Howe Sound above the sill, and a deep layer (70 m and below) that is contained north of the sill. Stratification in the upper layers varies seasonally, strengthening from May to August during freshet and with increased solar insolation and weakening from September through April with decreased river runoff and surface cooling. Stratification limits mixing between the surface and intermediate layers. Freshwater inputs from the Squamish River influence the salinity of the surface waters of the northern basin of Howe Sound. Variation in surface salinity is tied closely to the timing of freshwater inputs, where salinity is lowest during freshet and increases when freshwater inputs are reduced. Glacial melt flows from the Squamish River contribute high silt content and turbidity, especially during freshet. Mixing between the surface and intermediate layers is more likely enhanced in the winter months when stratification is weaker (Golder, 2015; BCELUCS, 1980).

In the northern basin, circulation in the upper two layers is estuarine-like due to outflow from the Squamish River, with a southward flowing current in the surface layer and a northward return flow in the intermediate layer (Thomson, 1981, Bell 1975). Currents in the surface layer are strongly influenced by wind (Buckley and Pond, 1976). Strong winds from inland are funneled down the Squamish Valley as discussed in Section 3.4.3. Tides in Howe Sound are semi-diurnal, with an average height difference of 3.2 m and a maximum height of 5 m, however they have little influence on surface circulation (Thomson, 1981). The general surface circulation pattern is shown in Figure 3-17, which notably bears resemblance to the silt patterns shown in the accompanying aerial photograph. Exchange with water in the southern extent of Howe Sound occurs on different timescales for each layer in the northern basin. In the intermediate layer, exchange with the Strait of Georgia occurs on the order of weeks and can be tidally modified near the sill (DFO, 2013). The deepest layer within the northern basin of Howe Sound exchanges with

water south of the sill periodically, approximately every 3-4 years (Bell, 1975). The deep water trapped in the basin can become strongly deoxygenated during its residence (Levings, 1980).

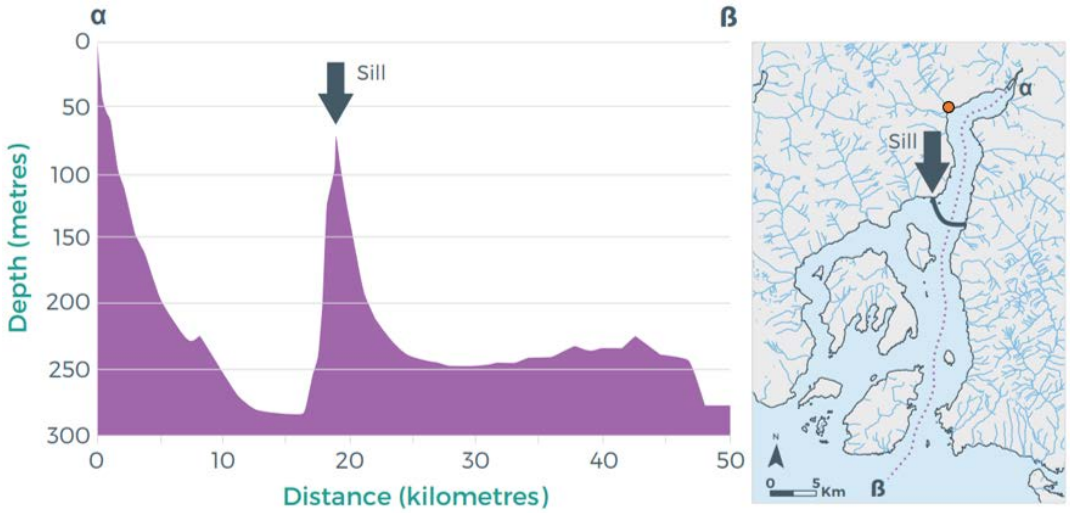

Figure 3-16: Cross-section of Howe Sound (left) along the north to south transect shown in the right figure. The approximate location of Woodfibre is indicated with an orange circle in the right figure. Figure modified from Ocean Watch (2017).

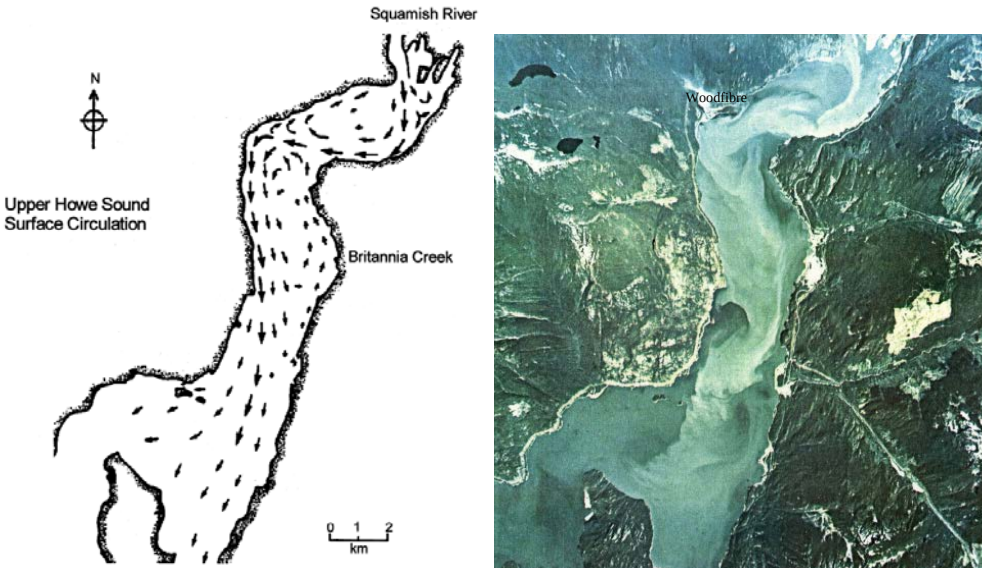

Figure 3-17: The current patterns of surface waters of the northern Howe Sound (left figure; Buckley & Pond, 1976). For comparison, the right figure shows the turbid outflow of the Squamish River waters in the northern extent of Howe Sound (August 7, 1972; Buckley, 1977).

Primary productivity in Howe Sound is relatively high compared to the Strait of Georgia, being highest to the south portion of the sound. This gradient in primary production is

largely influenced by down-fjord gradients in turbidity sourced from outflow of the Squamish River (Stockner, 1977). Further, primary production in Howe Sound has previously been limited near regions of anthropogenic influence. For example, increased turbidity from pulp mills (Stockner, 1976) and by acid mind drainage outflow (Levings, 2005) both limit primary productivity near the influence.

3.10.1 Water Column Study Results, 2013-2015

Studies on local current speed and direction, surface water elevation, and temperature through the marine water column in the Project area were conducted by Golder in 2014 and 2015 (Golder, 2015). A taut-line mooring was deployed May 2014 through May 2015 and was instrumented for the continuous measurement of currents, waves, conductivity and temperature. The mooring was located within the Project area, approximately 400 m southwest of Mill Creek (Figure 3-13). During the sampling period, the mooring was collected and re-deployed five times to service the instruments and remove entangled fishing equipment. The water column depth at the mooring was approximately 75 m to the seafloor. Typical current speeds were low in magnitude and typically less than 0.1 m/s with maximum current speeds measured at approximately 0.3 m/s. Local current direction is south-southwest during the ebb tide and north-northeast during the flood tide in the upper water column, approximately parallel to the shoreline.

In situ vertical water quality profiles were collected during the 2013 to 2015 monitoring programs (Golder, 2014 and 2015). Measured variables included temperature, specific conductance and conductivity, salinity, pH, oxidation reduction potential, dissolved oxygen, turbidity, and chlorophyll a. Vertical profile data was used to identify the depth of the pycnocline, which is the transitional layer between the freshwater influenced shallow and the deeper marine waters and is defined by a rapid change over depth in density, which is due to changes in temperature and/or salinity.

Water profiling showed evidence of stratification within the Project area, with higher turbidity and lower salinity shallow waters (up to 10 m depth) relative to higher salinity deeper waters (below 10 m depth). This is illustrated in Figure 3-18, which shows the July 2013 through May 2014 water column profiles southwest (stations WMB1, WMB4 and WMB7) and northeast (stations WMB9 and S-2) of Mill Creek (Golder, 2014). Water column stratification in Howe Sound is influenced by seasonal inputs from the Squamish River and nearby creeks, as previously described. Periods of high freshwater inputs in the summer reduce salinity and increase turbidity concentrations in a shallow surface layer, relative to depth, that extends from the mouth of Squamish River southward in Howe Sound waters and influences the shallow marine water quality within the Project boundaries southwest and northeast of Mill Creek as shown in the plots for May through September, 2014 (Figure 3-18).

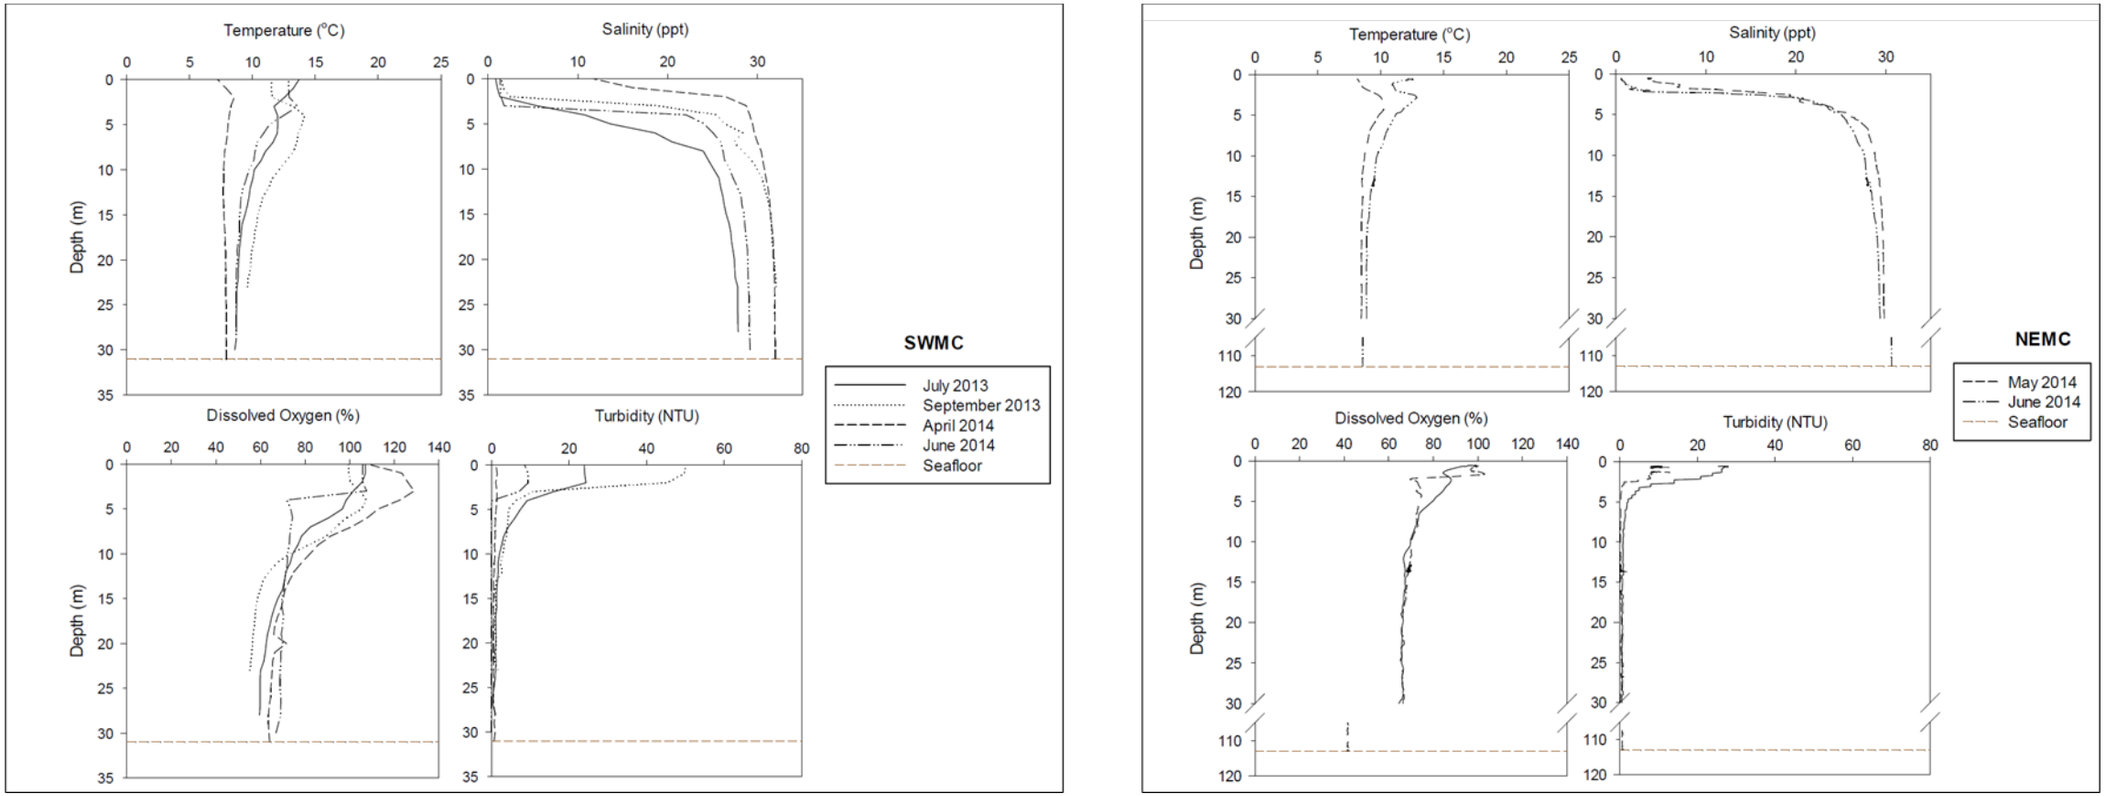

Figure 3-18: Marine Water Column Profiles for Temperature, Salinity, Dissolved Oxygen and Turbidity Southwest and Northeast of Mill Creek, SWMC and NEMC, respectively (from Golder, 2014).

3.10.2 Water Column Monitoring Results, 2022-2025

In situ water column profiling has been conducted alongside water quality sampling since February 2022. Profiling is conducted to record the structure of the water column at the time of sampling. Water column profiles of temperature, salinity, turbidity, dissolved oxygen, and pH were conducted using a YSI Sonde at one or more monitoring stations on a monthly basis from February 2022 to March 2024 and at a higher frequency (weekly to bi-weekly) from April 2024 onwards. The depth at the monitoring stations is between 15 to 30 m, and the upper 10 m of the water column is reliably captured in the monitoring program. Of the seven monitoring stations, five are located within the CPA (IDZ-W1, IDZ-W2, IDZ-E1, IDZ-E2, WQ1) and two are reference stations (WQR1 and WQR2) located approximately 500 m north and 500 m south of the CPA north and south boundaries. Heatmaps of in situ parameters were prepared to show seasonal changes to physical properties of the water column and are shown in Figure 3-19. Given the similar seasonal trends observed among stations located within the CPA and the marine reference stations, the heatmaps are an average of all water column profiles from all monitoring stations from February 2022 to October 2025. The data was averaged bi-weekly to highlight seasonal trends in the water column and only data in the upper 10 m of the water column are presented because of low data resolution below the 10 m depth.

This monitoring program provides insight into surface stratification and its seasonality in the ocean surrounding the Project site (Figure 3-19). The surface mixed layer, indicated by a large change in temperature or salinity near the surface, ranges from 5 to >10 m in depth depending on the season and is primarily influenced by seasonal variation of freshwater inputs. In the summertime the surface mixed layer is shallow (<5 m depth) and strongly stratified (having large a difference in salinity between the surface layer and the water column below it) owing to increased river runoff. The mixed layer deepens in the wintertime, increasing to an average of 7.5 m depth. This weakened wintertime stratification can allow for deeper vertical mixing in the upper water column.

The seasonal changes in salinity in the upper water column are largely dictated by riverine inputs to the region. During freshet, low salinity water (<20 ppt) occupies the upper 2 to 5 m of the water column, overlying saline water (20 to 32 ppt) below 5 m depth, consistent with the observations of Golder (2014). The deeper, saline layer is less seasonally affected compared to the surface mixed layer. Periods of low salinity in the upper water column are consistent with periods of high turbidity (30 NTU) in the upper 5 m of the water column. During periods of low Squamish River runoff, low salinity water remains only in the upper 2 m of the water column, and the water column becomes weakly stratified. Turbidity is typically low in the fall and winter when glacial melt ceases, except for heavy precipitation

events that increase riverine sediment loads (*e.g.* October 2024, Figure 3-19). As discussed above, high surface turbidity is a signature of runoff from the Squamish River (Figure 3-18 and Figure 3-19).

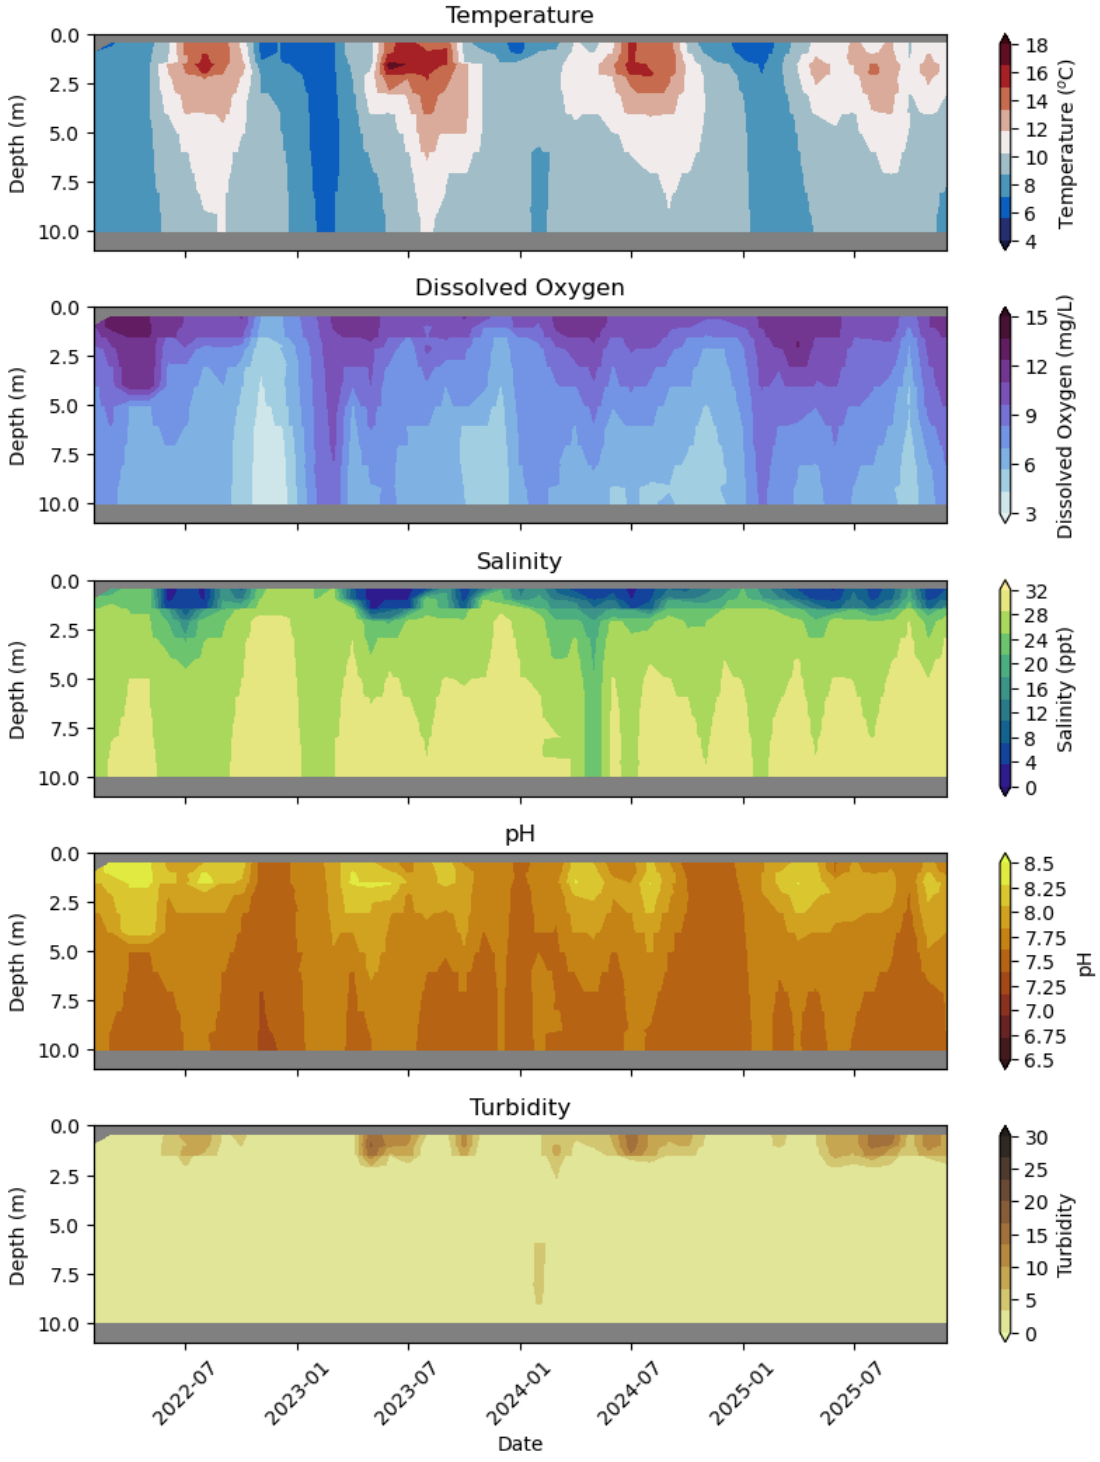

Figure 3-19: Heatmaps for Measured Variables at Stations Surrounding the CPA.

The results shown in Figure 3-19 also show seasonal trends in temperature, dissolved oxygen, and pH. Temperatures in the upper 10 m of the water column are largely influenced by solar radiation and, as such, vary seasonally. Surface mixed layer temperatures are highest in the summer, from May to September, reaching maximums of approximately 17^{o}C, and cool from October to March, reaching minimums of 6^{o}C. Water below the surface mixed layer is somewhat influenced by solar radiation but has less seasonal fluctuation. Surface dissolved oxygen concentrations vary inversely with temperature, due to solubility effects. Dissolved oxygen concentrations are highest in the late-winter and early spring, reaching maximums of 13 mg/L, and lowest in the summertime, reaching minimums of 8 mg/L in the surface mixed layer. The exception to this is the case of fall and winter upwelling events that can transport deeper, low oxygen waters to shallower depths in the water column (*e.g*. October and November 2022, Figure 3-19). There is slight seasonal variation in pH that pertains mostly to the surface mixed layer. In spring and summer, the surface layer has a slightly higher pH (8.0 on average) compared to below the surface layer (7.6 on average). In the winter months, the water column is well mixed and pH is circumneutral.

3.11 Marine Ecology

This section summarizes marine ecological conditions within the Project area. The Marine Fish and Fish Habitat Pre-Construction Baseline Report prepared by Keystone (2024a) summarizes field studies conducted from July 2013 to November 2023. These studies included marine riparian, intertidal, and subtidal surveys to document habitat type and use, substrate composition, and biota.

Since the start of construction in November 2023, monitoring has been carried out in accordance with the Marine Fish and Fish Habitat Environmental Effects Monitoring Plan (Keystone, 2025a). Results from the first year (*i.e*., 2024) of Environmental Effects Monitoring (EEM) are presented in Keystone (2025a). Marine ecology is further assessed as part of the Aquatic Effects Assessment for the Second Floating Worker Accommodation (Floatel #2) (Keystone, 2025b). Key findings from the above-mentioned reports are summarized herein to characterize conditions prior to operation of the LNG facility.

3.11.1 Biophysical Habitat

Biophysical surveys showed low abundance and diversity of marine biota in the intertidal and subtidal zones within the Project area boundaries (Keystone, 2024a). The intertidal zone is characterized by hard substrate and a band of rockweed occupying large boulders that are infrequently disturbed by wave actions. Below the rockweed band, sparse patches of sea lettuce and laminarian kelp were observed. Sightings of invertebrates (*e.g.*, acorn

barnacles, blue mussel, shore crabs) were infrequent and limited to riprap and boulders within the intertidal zone. The subtidal zone is characterized by soft sediment comprised of wood debris, sand, and silt. Compared to the intertidal zone, the subtidal zone was inhabited by less macroalgae (*e.g.*, kelp) but more benthic invertebrates (*e.g.*, anemones, sea urchin). The presence of an infauna community within the subtidal sediments was inferred from the observed invertebrate holes, fecal casings, and bivalve shells.

3.11.2 Pacific Herring and Lingcod Spawning

Pacific herring spawning dive surveys have been conducted for seven years over the 2015 to 2023 period and spawn was observed within the Project area in four of those years (2015, 2016, 2019, and 2021) (Keystone, 2024a). The 2015 and 2016 surveys found spawn on pilings that were removed prior to the 2019 survey. During construction in 2024, herring spawn was observed on rockweed and sugar kelp (Keystone, 2025a). Overall, the surveys determined that spawning habitat is marginal within the Project area, with spawn observations generally limited to a narrow band on rocky substrate that is covered by rockweed and kelp in the intertidal and shallow subtidal zones (Keystone, 2024a; Keystone, 2025a).

During herring dive surveys conducted since 2015, lingcod egg masses were also observed among boulder substrate and crevices between pilings within the Project area (Keystone, 2024a). Repeated observations of egg masses in the northeast corner of the Project area suggest this area is frequently used by lingcod for spawning.

3.11.3 Fish Presence and Migration

Fish presence surveys conducted within the marine area of the Project showed presence of Pacific salmonids, forage fish (*e.g.*, Pacific herring), and other demersal and pelagic fish (Keystone, 2024a). Sampling was focused on late spring and summer months, which showed prevalence of chum and pink salmon in late March, and chinook and coho salmon in June and July. However, the Pacific herring larvae that hatched in Howe Sound may disperse to the Project marine area from February to June. Sampling and anecdotal evidence suggest that Northern anchovy, a forage fish, may be present within and adjacent to the Project marine area from April to September, but have not been observed to spawn within in the Project area.

Mill Creek and Woodfibre Creek serve as spawning and rearing habitats for salmonids. Biennial migrations of pink salmon occur from August to October (peak in September), with higher number of spawners observed in Mill Creek than Woodfibre Creek. There were anecdotal observations of chum salmon spawners in Mill Creek in November 2022. Coho spawning was not observed during baseline monitoring. Mill Creek and Woodfibre Creek

host populations of juvenile chinook and coho salmon, rainbow trout, and sculpin. Mill Creek also supports populations of juvenile chum salmon.

3.11.4 Marine Mammals and Species at Risk

Howe Sound is regularly visited by marine mammals, including whales, dolphins, porpoises, sea lions, and harbour seals (Lorax, 2023). The presence of marine mammals and species at risk in the Project marine area was evaluated in Keystone (2025b) based on a desktop review of publicly accessible databases, published literature, and site-specific monitoring programs such as the Marine Mammal Management and Monitoring Plan (Stantec, 2023) and the Marine Mammal Observation Program Review for 2024–2025 MLRW (WLNG, 2025). The likelihood of aquatic species at risk (*e.g.*, bluntnose six gill shark, green sturgeon) to be present within the Project boundaries or surrounding area is considered low or low to moderate (Keystone, 2025b).

3.11.5 Aquatic Invasive Species

Surveys for aquatic invasive species were conducted in and adjacent to the Project area boundaries in 2022 and 2023 (Keystone, 2024a) to look for the presence of sessile invertebrates and European green crab that may be introduced through commercial shipping activities (*e.g.*, ballast water discharge). No occurrences of aquatic invasive species were reported within in the survey area during baseline monitoring.

3.11.6 Potential Project Influence

Potential project influence from construction activities is monitored via the EEM and is assessed using key performance indicators (KPIs), as defined in the Marine Fish and Fish Habitat Environmental Effects Monitoring Plan (Keystone, 2025a):

- KPI1: Change in fish behaviour – Pacific herring spawning
- KPI2: Change in fish abundance – presence and migration through the CPA
- KPI3: Change in fish behaviour – salmon spawning and outmigration from Mill Creek
- KPI4: Introduction of invasive species from ballast water exchange

Results from the first year (*i.e.*, 2024) of EEM are detailed in Keystone (2025a) and did not indicate discernable changes to KPIs compared to pre-construction conditions.

4. Effluent Discharges

4 Effluent Discharges

This section describes the water management and contact water treatment strategies that will be used during operation of the LNG facility. The implementation of the operations stormwater and contact water management system is outlined, including how construction water management will transition to the operations water management systems. The water balance, water quality, and receiving environment mixing models developed for the Project are presented. The models are used to simulate the expected quantity and quality of contact water and to characterize the mixing of contact water discharges in the Howe Sound receiving environment.

The water management approach, including the site hydrology model, water management system design, and system implementation are discussed in Section 4.1. The OWTS design is presented in Section 4.2, with a technical description of the treatment system components and how the OWTS will be operated. Section 4.3 describes modelling conducted to predict the quantity and quality of contact water discharges and presents the model results. The description and results of the receiving environment mixing model are provided in Section 4.4.

4.1 Water Management

The processes and facilities that will be used to manage water during commissioning and operation of the Project are described in this section. Stormwater is the primary source of water that will discharge from the site. A small amount of vehicle wash water will also be produced and will be managed within the water management system. The objectives of the water management system are to minimize the amount of stormwater that contacts Project facilities and ground surfaces, and to manage water conveyance and discharge in a manner that is safe for workers, prevents damage to Project infrastructure, and prevents harm to the receiving environment.

WLNG has developed an Operations Stormwater Drainage Management Program (SWDMP), which outlines the strategies for managing the stormwater drainage system during operations. The program includes descriptions of stormwater drainage management strategies and plans, OWTS operations and residuals management, contingency measures for non-compliant water or OWTS interruptions, episode management for natural events, trigger and response protocols for water quality exceedances, and an adaptive management approach to address uncertainties and ensure ongoing compliance. The SWDMP is provided as Appendix 4.1-1. A brief overview of each management plan is provided in the sub-sections below.

The SWDMP describes the water management infrastructure (*e.g.,* diversion ditches, sumps, outfalls) that will be in place during operations. In addition, the SWDMP summarizes the different categories of surface water runoff (*e.g.,* non-contact water and contact water) and outlines how each is managed to prevent project-related environmental impacts. This information is presented in Section 2.0 of the SWDMP (Appendix 4.1-1).

Water controlled by the water management system is classified into various water types that will be segregated and conveyed using a system of sumps, ditches, swales, trenches, pipelines and culverts prior to discharge to the Howe Sound and Mill Creek receiving environments. Mitigations will be implemented to identify water that is contaminated and requires containment. On-site treatment for TSS and extractable petroleum hydrocarbons (EPH) using Stormceptors, and an OWTS will also be implemented. The overall layout of the water management system is provided in Figure 2-1.

Water management conveyance structures are sized in accordance with District of Squamish Subdivision and Development Control Bylaw No. 2649, 2018 (Schedule B Design Criteria, Section 4.0 – Stormwater Management). Minor conveyance systems (*i.e.,* concrete trenches, underground stormwater pipes and catch basins) are sized for runoff from the 1-in-10 year return period, and major systems (*i.e.,* sheet flow on roads and walkways, diversion ditches, open channels and culverts) are sized for the 1-in-100 year return period (MDR 2026b or Appendix 4.1-2). The influences from rain-on-snow and climate change are accounted for in the rainfall values used for the design of water management facilities. Drawings showing the civil standards for ditches, swales, trenches and outfall headwalls are included in Appendix 4.1-3.

4.1.1 Water Type Classification

The water management system will intercept and convey stormwater that originates from outside of the Project site, stormwater that contacts the Project site, and water that is generated within the site during facility operations. Flows in the lower reaches of East Creek are managed through channels and culverts that were upgraded during construction. The various water types are classified based on the areas from which the water originates. The water type classification and definitions adapted from the SWDMP (Appendix 4.1-1) are provided in Table 4-1.

Table 4-1:
Water Type Definitions

Water Type	Definition
Stormwater	Water from precipitation that results in overland runoff outside and inside the Project site.
Non-Contact Water	Water generated from outside the footprint of the LNG Facility which does not come into contact with any part of the facility before entering the receiving environment. This also includes water originating from undeveloped / non-developable periphery areas of the site located along the creeks and Howe Sound shoreline, which drains directly to those water bodies.
Contact Water	Water generated from within the facility footprint either naturally or from facility operations. Contact water is further divided into three classifications as outlined below.
Contaminated Contact Water	Water originating from operational process areas, such as the amine unit, hydrocarbon loading/unloading stations, hydrocarbon storage areas, and any other areas surface runoff contacts oil drips from oily equipment base plates, lubrication skids, and piping drains.
Potentially Contaminated Contact Water	Water which potentially comes into contact with the LNG process and other process areas. This water is collected in the paved areas beneath the process modules and equipment.
Non-Contaminated Contact Water	Water originating from within the facility area which does not come into contact with any potential contaminant sources.

4.1.2 Parameters of Potential Concern (POPCs)

Parameters of potential concern (POPCs) have the potential to cause pollution in the receiving environment. The POPCs for the Project originate from process reagents and oil products that will be used in Project equipment and machinery, as well as from LNG and condensate that is produced by the Project, equipment wash water, and loose sediment particulates that may be present on infrastructure or ground surfaces. Stormwater may mobilize drips of reagent and oils within the LNG Processing Area (Figure 2-2), as well as loose sediment particles (*i.e.,* TSS) that may have settled on Project facilities and ground surfaces or be associated with equipment wash water. Oils are monitored using the EPH parameter (ENV, 2023); therefore, the POPC for oil products is identified as EPH. Planned management approaches for POPCs in contact water include secondary containment, evaporation, off-site disposal, on-site treatment with the OWTS, installation of surfacing materials that minimize sources of loose particulates, and the use of EPH and TSS traps (*i.e.*, stormceptors) in the contact water drainage system.

The SWDMP (Appendix 4.1-1) and the Operations Phase Best Achievable Technology Assessment (BATA) (MDR, 2026b; Appendix 4.2-1) identify sources of POPCs in contact water and explain how management approaches will be implemented for each POPC. A summary of POPCs and their associated management approaches are listed in Table 4-2.

Table 4-2:
Summary of Parameters of Potential Concern (POPCs) and Associated Management Approach

Source	Description	POPC	Management Approach
Diesel	Fuel for vehicles, firewater pump engines and essential generators.	EPH, PAHs	Secondary containment, off-site disposal
Heating Medium (Dowtherm Q)	Heat transfer fluid managed in the Process Utility Module (M09)	EPH	Secondary containment, off-site disposal
Lubricating oils, and greases	Oils and greases used in rotating equipment and lubricating skids throughout the LNG Processing Area	EPH	Secondary containment, treat with OWTS
Hydraulic oils	Oil used in hydraulic equipment in the Marine Terminal Area	EPH	Secondary containment, treat with OWTS
Dielectric oil	Oil used to cool electrical transformers within the Powerhouse Modules (M10/M11)	EPH	Secondary containment, off-site disposal, or treat with OWTS
Wash Water	Vehicle wash water and LNG Processing Area cleaning.	EPH, TSS, metals and detergents	Secondary containment, treat with OWTS. Use biodegradable, self de-emulsifying detergent.
LNG	LNG process product that is predominantly methane.	Trace amounts of volatile petroleum hydrocarbons and non-halogenated VOCs (BTEX)	Secondary containment, disperse by evaporation.
Condensate	Heavier natural gas components extracted before LNG is liquified. Primarily pentane and heavier volatile petroleum hydrocarbons.	Volatile petroleum hydrocarbons such as pentane, VH(C6-10), and non-halogenated VOCs (BTEX).	Secondary containment, disperse by evaporation or off-site disposal
Amine (OASE Purple)	Acid gas removal reagent (>70% methyldiethanolamine), used to remove carbon dioxide and other impurities from the natural gas feedstock in the Pre-Treatment Module (M01).	Amine (methyldiethanolamine)	Secondary containment, off-site disposal
Tempered water	Coolant (inhibited ethylene glycol, 40%) used to cool rotating equipment and compressors	Ethylene glycol	Secondary containment, off-site disposal
Chlorinator for fire water / service water	A basket-type chlorinator is located downstream of the Fire Water Tank.	Chlorine	Chlorine tablets are periodically used at dosages consistent with industry best practices to prevent algae growth in the Fire Water Tank.
Non-contaminated stormwater	TSS from gravel covered areas, as well as metals and PAHs that may be associated with TSS.	TSS, metals and PAHs	TSS controls. Use compacted gravels on level surfaces, rip-rap or vegetation on slopes, and Stormceptor oil/grit separators. Frequently trafficked areas are paved with asphalt or concrete.
	Low pH (*e.g.*, pH 5.5) is a natural condition in non-contact water and is expected to be similarly low in contact water runoff. Refer to Section 3.6.3.1.	pH	Not applicable – natural background condition.

The BATA (MDR, 2026b; Appendix 4.2-1) identified TSS and EPH as parameters of concern (POCs) that will be mitigated by on-site treatment. All other POPCs will be managed through off-site disposal (process reagents or products) or evaporation (volatile petroleum hydrocarbons and non-halogenated VOCs). During typical operation, there are no activities within the Project site that will produce TSS. There will be little to no traffic in gravelled areas, and properly graded rip-rap or compacted gravel will be used to minimize the risk of erosion in gravel covered areas that would cause TSS migration to stormwater. It is expected that TSS may settle in the Oily Water Storage Tank, primarily from wash water, and may be re-suspended when the pump to the OWTS is started. Therefore, to prevent the short-term discharge of effluent with elevated TSS concentrations, the OWTS is designed to manage TSS as described in Section 4.2.

Lubricating, hydraulic and dielectric oils are also referred to as petroleum hydrocarbons. These products are mixtures of organic compounds that typically contain hundreds of individual organic compounds. Testing for the presence of oil in environmental samples is commonly conducted by measuring the mixture as a single aggregate parameter. It is important to note the aggregate parameter for measuring oil in environmental samples is defined by a test procedure that varies slightly between regulatory jurisdictions. In B.C., the aggregate parameter for oil, EPH, is defined by the test methods for EPH in soil and water (ENV, 2023). Therefore, the aggregate parameter as defined in B.C. (*i.e.*, EPH) is identified as the POPC and POC for oil products that will be used at the Project site.

Alternative definitions for EPH include total petroleum hydrocarbons (TPH) (ENV, 2023), petroleum hydrocarbons (PHC) fraction 2 to fraction 4 (F2-F4) (CCME, 2008), and diesel range organics (DRO) (US EPA, 2003). The main difference between the various definitions is the range of individual compounds included in the aggregate parameter, although the presence or absence of certain steps in the test procedure (e.g., silica gel cleanup) will also affect the final concentration that is reported. Each of the compounds in an oil product can be defined by the number of carbon (C) atoms it contains. By convention, the aggregate parameter is bracketed by two specific compounds that contain a different number of C atoms. For example, EPH is bracketed by compounds that contain 10 and 32 C atoms, whereas F2-F4 and DRO are bracketed by compounds with 10 and 34 C atoms, and 10 and 28 C atoms, respectively. Therefore, although the various aggregate parameters are all suitable for detecting oil in environmental samples, there are differences in the compounds within the oil mixture that are included in the measured value for each aggregate parameter.

4.1.3 Outfall Catchments

Water management will be implemented for contact water and non-contact water. Contact and non-contact water will discharge through outfalls to Howe Sound or Mill Creek. Each of the outfalls is identified by the outfall code (OUT) and a unique number. Non-contact and non-contaminated contact water will discharge to the receiving environment through OUT-01, OUT-02, OUT-04, OUT-06, OUT-11, OUT-12, and OUT-13. Water contaminated with EPH and TSS will be treated in the OWTS prior to discharge at OUT- 10. Figure 4-1 and Figure 4-2 provide an overview of the water types within the catchment of each outfall. Figure 4-2 also illustrates how the OWTS is integrated into the management of water contaminated with EPH and TSS. The stormwater catchment areas for each outfall are derived in the Operations Phase Stormwater Drainage Hydrology and Hydraulics Model (Appendix 4.1-2) and the physical extent of the catchments are shown in Figure 4-3.

TITLE:

Outfall Catchments and Project Contact Water Catchment Areas

PROJECT #: A825-1 *FIGURE:* 4-3

Printed by: DesMacDonald

Figure 4-03 Woodfibre LNG Site Catchments_V2

P:\@2025061\Woodfibre\Drafting Figures\APRX\WLNG Catchments\Site Catchments.aprx

The contact water catchment areas for the Project are within the black dashed boundary lines shown in Figure 4-3. Areas outside the dashed black boundary lines are defined as non-contact areas. The contact water catchments include roads, gravel covered areas, paved areas, concrete covered areas and the land-based Project facilities described in Section 2.1. High traffic roads within the contact water catchment areas are paved with asphalt. The LNG Processing Area, Refrigerant and Condensate Storage Area, and Industrial Area facilities (Figure 2-2) are underlain by impermeable surfaces such as asphalt or concrete. Slopes and areas not used for Project facilities, and infrequently used or inaccessible areas within the contact water catchments, are covered in gravel and crushed rock.

The catchment characteristics and water types discharged from each outfall are described in the stormwater drainage flow model (Appendix 4.1-2) and summarized below:

- OUT-01: Discharges through a 900 mm diameter culvert to Howe Sound. The 30.97 ha catchment is predominantly non-contact water from offsite forested areas (30.76 ha), with the small inputs of non-contaminated contact water from gravel and impervious surfaces (0.14 and 0.07 ha, respectively).
- OUT-02: Predominantly non-contact water from offsite forested areas (22.45 ha). Non-contaminated contact water from a relatively small catchment within the Industrial Area consisting of gravel and impervious surfacing (1.59 and 1.18 ha, respectively) is conveyed by trench drains, ditches and swales to this outfall. The Fire Water Tank water filtration system backflush is periodically discharged to the OUT-02 water management ditch immediately south of the tank. All the conveyed water passes through Stormceptor STC-01 prior to discharging to Howe Sound though a 900 mm diameter culvert. The total catchment area is 25.22 ha.
- OUT-04: The 2.37 ha catchment is entirely non-contaminated contact water (stormwater) from gravel and impervious surfaces (0.93 and 1.44 ha) within the Industrial Area. The stormwater is collected in a network of storm drains and pipes and passes through Stormceptor STC-02 prior to discharging to Howe Sound via a conveyance ditch and culvert.
- OUT-06: Primarily non-contact water from hillside forested areas (8.05 ha) and a small catchment of non-contaminated contact water (stormwater) from gravel and impervious surfaces (0.66 and 0.24 ha, respectively) located in the Industrial Area. Drainage from the total catchment area of 8.95 ha is conveyed by a diversion ditch to Mill Creek via a culvert.
- OUT-10: The catchment for this outfall includes contaminated and potentially contaminated water from the LNG Processing Area, the Refrigerant and Condensate Storage Area, and non-contaminated areas. The water management

system segregates the three types of contact water (non-contaminated, potentially contaminated and contaminated). The discharge to Howe Sound is non-contaminated contact water and OWTS treated effluent, both of which are conveyed via Stormceptor STC-03 to the discharge culvert. The total catchment area is 7.36 ha and is surfaced with gravel (4.36 ha) and impervious materials (3.00 ha).

- OUT-11: The majority of the 4.69 ha catchment is from hillside non-contact water (3.66 ha) and non-contaminated contact water from gravel and impervious surfaces (0.58 and 0.45 ha, respectively) that extend from the diversion ditch to approximately the centre of the LNG Processing Area perimeter road adjacent to the diversion ditch. The outfall culvert discharges to Howe Sound.
- OUT-12: East Creek discharges to Howe Sound through this outfall via two culverts. The creek catchment is predominantly non-contact water from forested areas (55.87 ha), and non-contaminated contact water from gravel roads and impervious surfaces (5.00 and 1.24 ha, respectively).
- OUT-13: Intercepts primarily non-contact water from forested areas (2.61 ha) and non-contaminated contact water from an access road (0.07 ha), and discharges to Howe Sound.

4.1.4 Stormwater Flow Modelling

Hydrology and hydraulic modelling for stormwater runoff was conducted for the Project site as described in the Operations Phase Stormwater Drainage Hydrology and Hydraulics Model (Appendix 4.1-2). The modelling results were used to inform the design specifications for the stormwater conveyance structures (i.e., ditches, culverts and outfalls). The Personal Computer Storm Water Management Model software was used for modeling stormwater drainage. The model incorporated Intensity-Duration-Frequency (IDF) curves presented in the Woodfibre Hydrometeorology Baseline Report (Stantec, 2020) that account for climate change and the influence of regional topography.

Three types of rainfall durations and distributions were evaluated, specifically:

1. The Soil Conservation Service Type 1A distribution with 24-hour duration;
2. The Atmospheric Environmental Service distribution with 2-hour duration; and
3. Atmospheric Environmental Service (AES) distribution with 2-hour duration.

Of these, the Soil Conservation Service Type 1A distribution with 24-hour duration combined with the rain-on-snow IDF curve yielded the highest flow rates and was therefore used for developing the design of the stormwater runoff conveyance facilities,

Stormceptors, and outfall structures (Table 4-3). The influence of climate change was accounted for by using the maximum value predicted by the following two approaches:

1) Precipitation depth estimated by the University of Western Ontario Computerized Tool for Development of IDF Curves Under a Changing Climate (Version 4.0) for the Squamish Airport under the moderate intensity scenario (RCP 4.5); and
2) Precipitation depth based on the historical IDF curve for Squamish Airport, plus 10%, in accordance with the Engineers and Geoscientist British Columbia Professional Practice Guidelines for Legislated Flood Assessments in a Changing Climate in B.C. (Version 2.1).

Table 4-3:
Intensity-Duration-Frequency Table for Mill Creek, Woodfibre Creek and East Creek Watershed with Climate Change Considerations (Stantec, 2020)

Duration	Return Period Precipitation Depth (mm)		
	2-year	10-year	100-year
5 minute	2.9	6.5	15.4
10 minute	4.1	8.3	17.8
15 minute	5.1	9.1	17.8
30 minute	7.8	11.6	18.7
1 hour	13.2	18.5	29.1
2 hour	21.3	28.8	41.3
6 hour	47.1	66.8	99.5
12 hour	78.1	112.2	148.5
24 hour	126.8	187.1	257.8
24 hour (rain on snow)	157.0	221.6	297.2

The final surfacing within the outfall catchments will consist of impervious surfaces (*i.e.*, concrete and asphalt), gravel, and forested areas. Ground infiltration is accounted for in the hydraulic model using the United States Natural Resources Conservation Service Curve Number method, which considers the effect of both land use, cover and soil type. The catchment for each outfall is subdivided into impermeable surfaces (*i.e.*, asphalt, concrete and buildings), gravel covered surfaces, and forested areas to account for ground infiltration. The total catchment area with a breakdown of the three surface types, and modelled peak flows for 10-year and 100-year return periods, are summarized in Table 4-4.

Table 4-4:
Modelled Catchment Areas and Flows for Stormwater Outfalls

	OUT-01	OUT-02	OUT-04	OUT-06	OUT-10	OUT-11	OUT-12	OUT-13

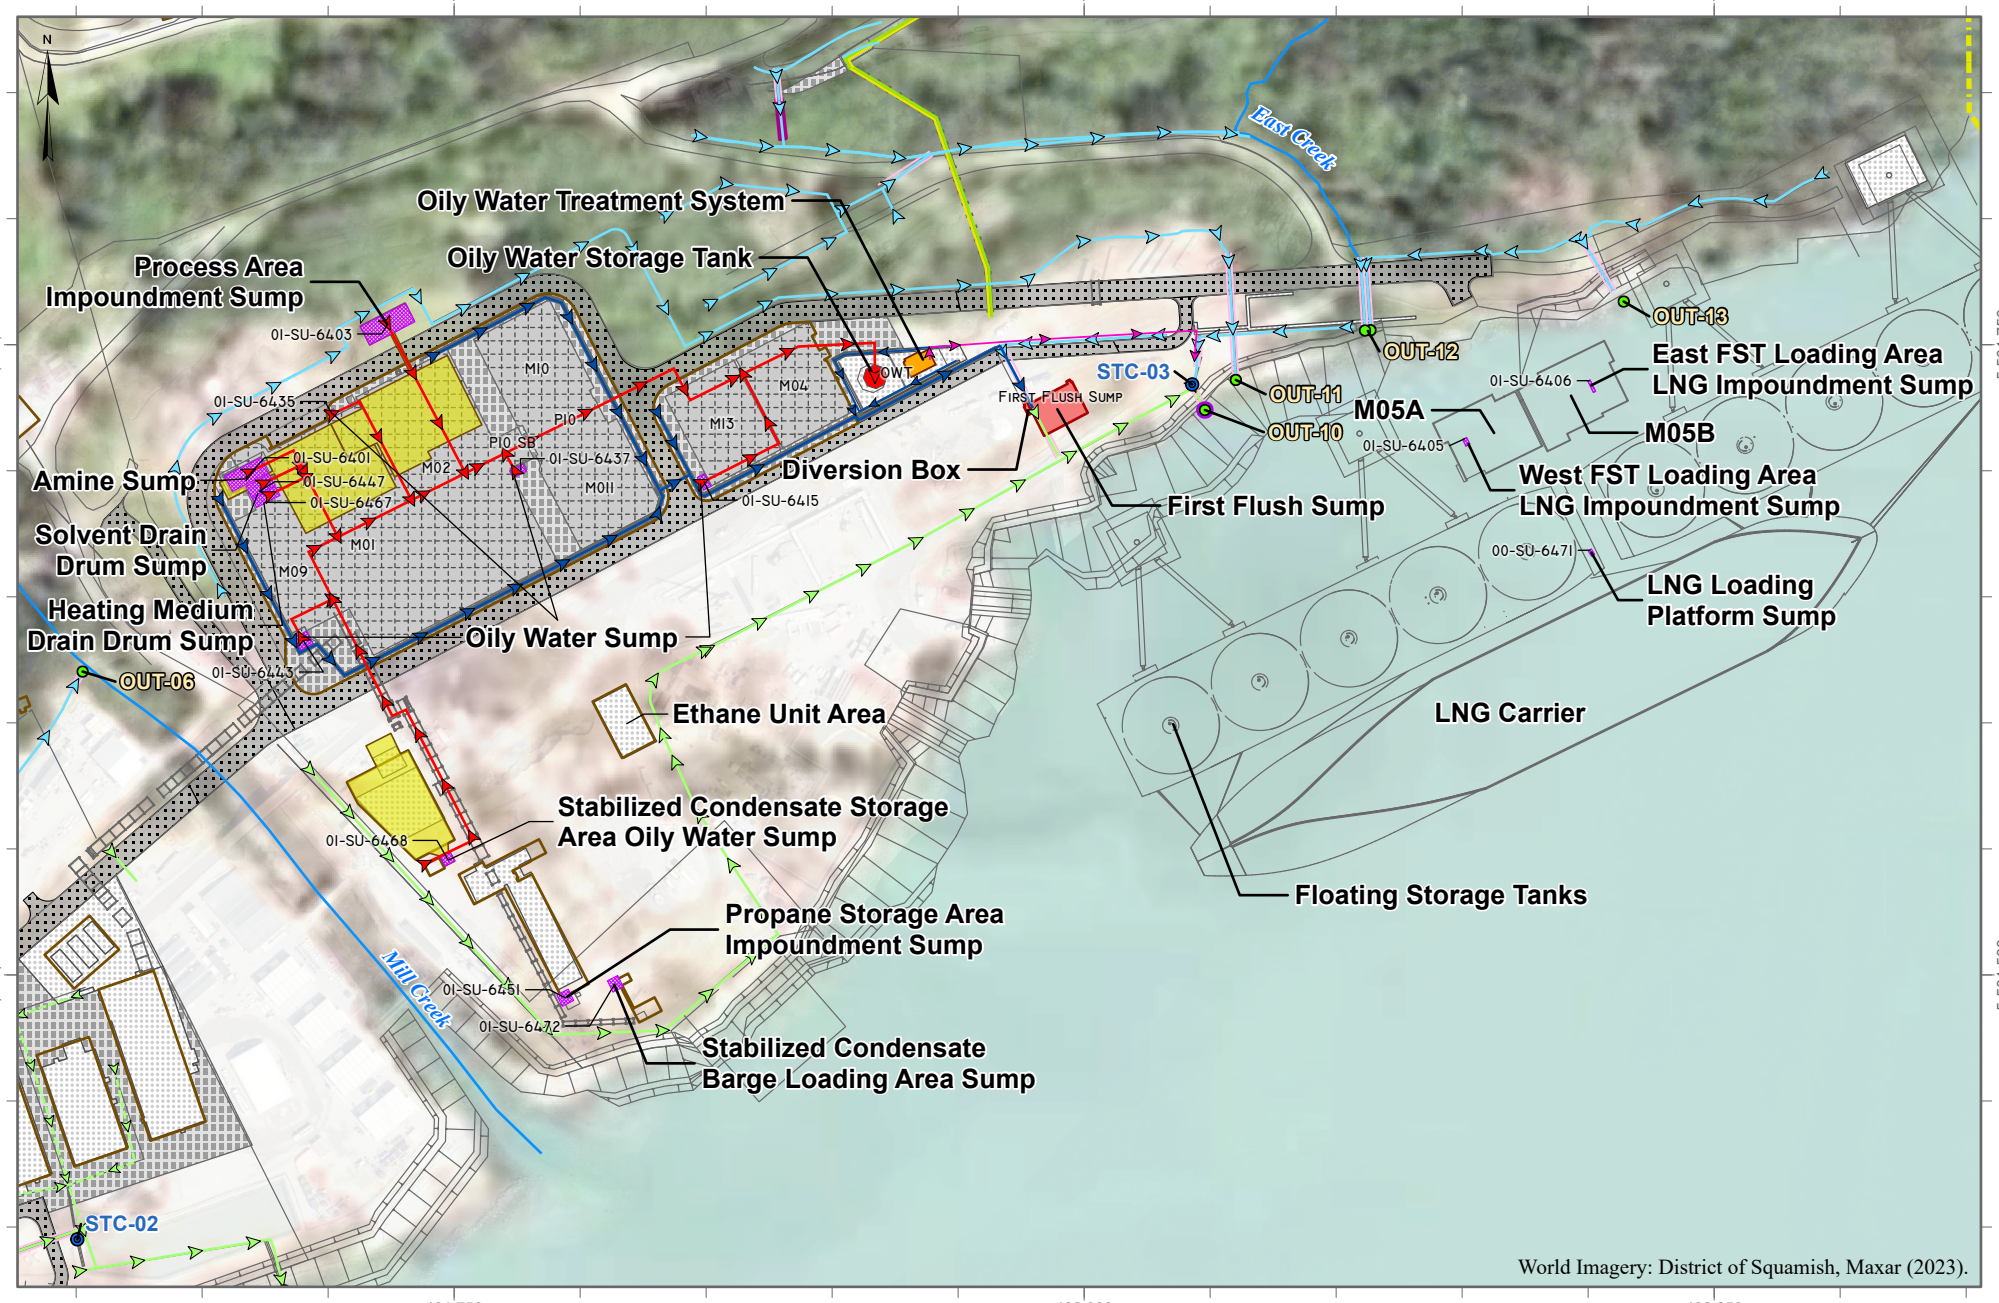
1-in-100 Year 24-Hour Peak Flow (m^3/s)	1.70	1.40	0.20	0.49	0.61	0.32	3.66	0.16

[1] The OUT-13 impervious area is a gravel access road, not an impervious surface as was assumed in the hydraulic model. This table is reproduced from the hydraulic model (Appendix 4.1-2). For consistency, the area assignment has not been altered.

4.1.5 Stormwater Management System

The stormwater water management system is designed to manage stormwater from outside and inside the Project site as outlined in the Storm Water Drainage Philosophy document (MDR, 2026a), the Unit 64 Effluent and Wastewater System Process Design Basis (MDR, 2025c; Appendix 4.2-2), and the SWDMP (Appendix 4.1-1). The approximate stormwater catchment areas managed by the system, as well as the boundary of the Project contact water areas, are shown in Figure 4-3. The water management system layouts east and west of Mill Creek are shown in Figure 4-4 and Figure 4-5, respectively. The water management process flow diagram is shown in Figure 4-6.

The water management infrastructure includes ditches, swales, trenches, storm sewers, culverts, sumps, a storage tank, a treatment system, and vacuum trucks. Non-contact water is intercepted and diverted around the Project site to Howe Sound and Mill Creek. Contact water is managed based on the risk of contamination associated with Project activities. Contact areas with low risk of contamination (because they are outside of areas where process liquids could be spilled) are considered non-contaminated, and those with a higher risk or known contamination are managed as potentially contaminated or contaminated areas, respectively. Therefore, stormwater collection and conveyance systems are established for each of the contact water sub-areas to achieve stormwater management and source control objectives:



- Contaminated contact water system;
- Potentially contaminated contact water system; and
- Non-contaminated contact water systems.

Source control measures to detect and isolate process fluids that contain POPCs and POCs (Section 4.1.2) for appropriate disposal are integrated into each of the water collection systems. The contaminated contact water system is designed to collect and convey oily water to the OWTS for treatment. Secondary containment is implemented in areas where process fluids are used within the potentially contaminated and non-contaminated contact water systems. The contact water stored in secondary containment is evaluated for the presence of POCs and POPCs listed in Table 4-2 (Section 4.1.2), and if detected, the contact water is managed according to the type of POPC that is present:

- Oily water (lubrication oils, hydraulic oils) is directed to the Oily Water Storage Tank;
- Contaminated contact water that contains sources of POPCs that are flammable (ethane, propane, condensate, LNG) is held back to allow these products to safely disperse through evaporation prior to releasing the contact water to the water management system. Otherwise, these waters are collected by a vacuum truck for off-site disposal.
- Contaminated contact water containing other POPCs (amine, Dowtherm Q, ethylene glycol, diesel) is collected from containment areas by vacuum truck for off-site disposal.

4.1.5.1 Contaminated Contact Water System

The contaminated contact water system is located in the LNG Processing Area (refer to Figure 2-2) and is designed to manage contact water that can be treated for oil (*i.e.,* EPH). The system consists of oily water collection piping, containment areas, sumps, pumps, storage, and treatment. The system layout is shown in Figure 4-4. The sumps collect drainage from the oily water collection systems and containment areas, and the collected contact water is conveyed to the appropriate water management system based on the presence or absence of POCs or POPCs. Oily water from containment areas east of Mill Creek that are not connected to the contaminated contact water pipeline are transferred to the Oily Water Storage Tank by vacuum truck. Oily water from diesel fuel containment areas west of Mill Creek is collected for off-site disposal. The OWTS treats water from the Oily Water Storage Tank for oil (*i.e.,* EPH) and TSS, and discharges treated effluent to the non-contaminated contact water system which discharges to Howe Sound at OUT-10. A detailed description of the OWTS is provided in Section 4.2. Additional details for the sumps and collections systems are described below:

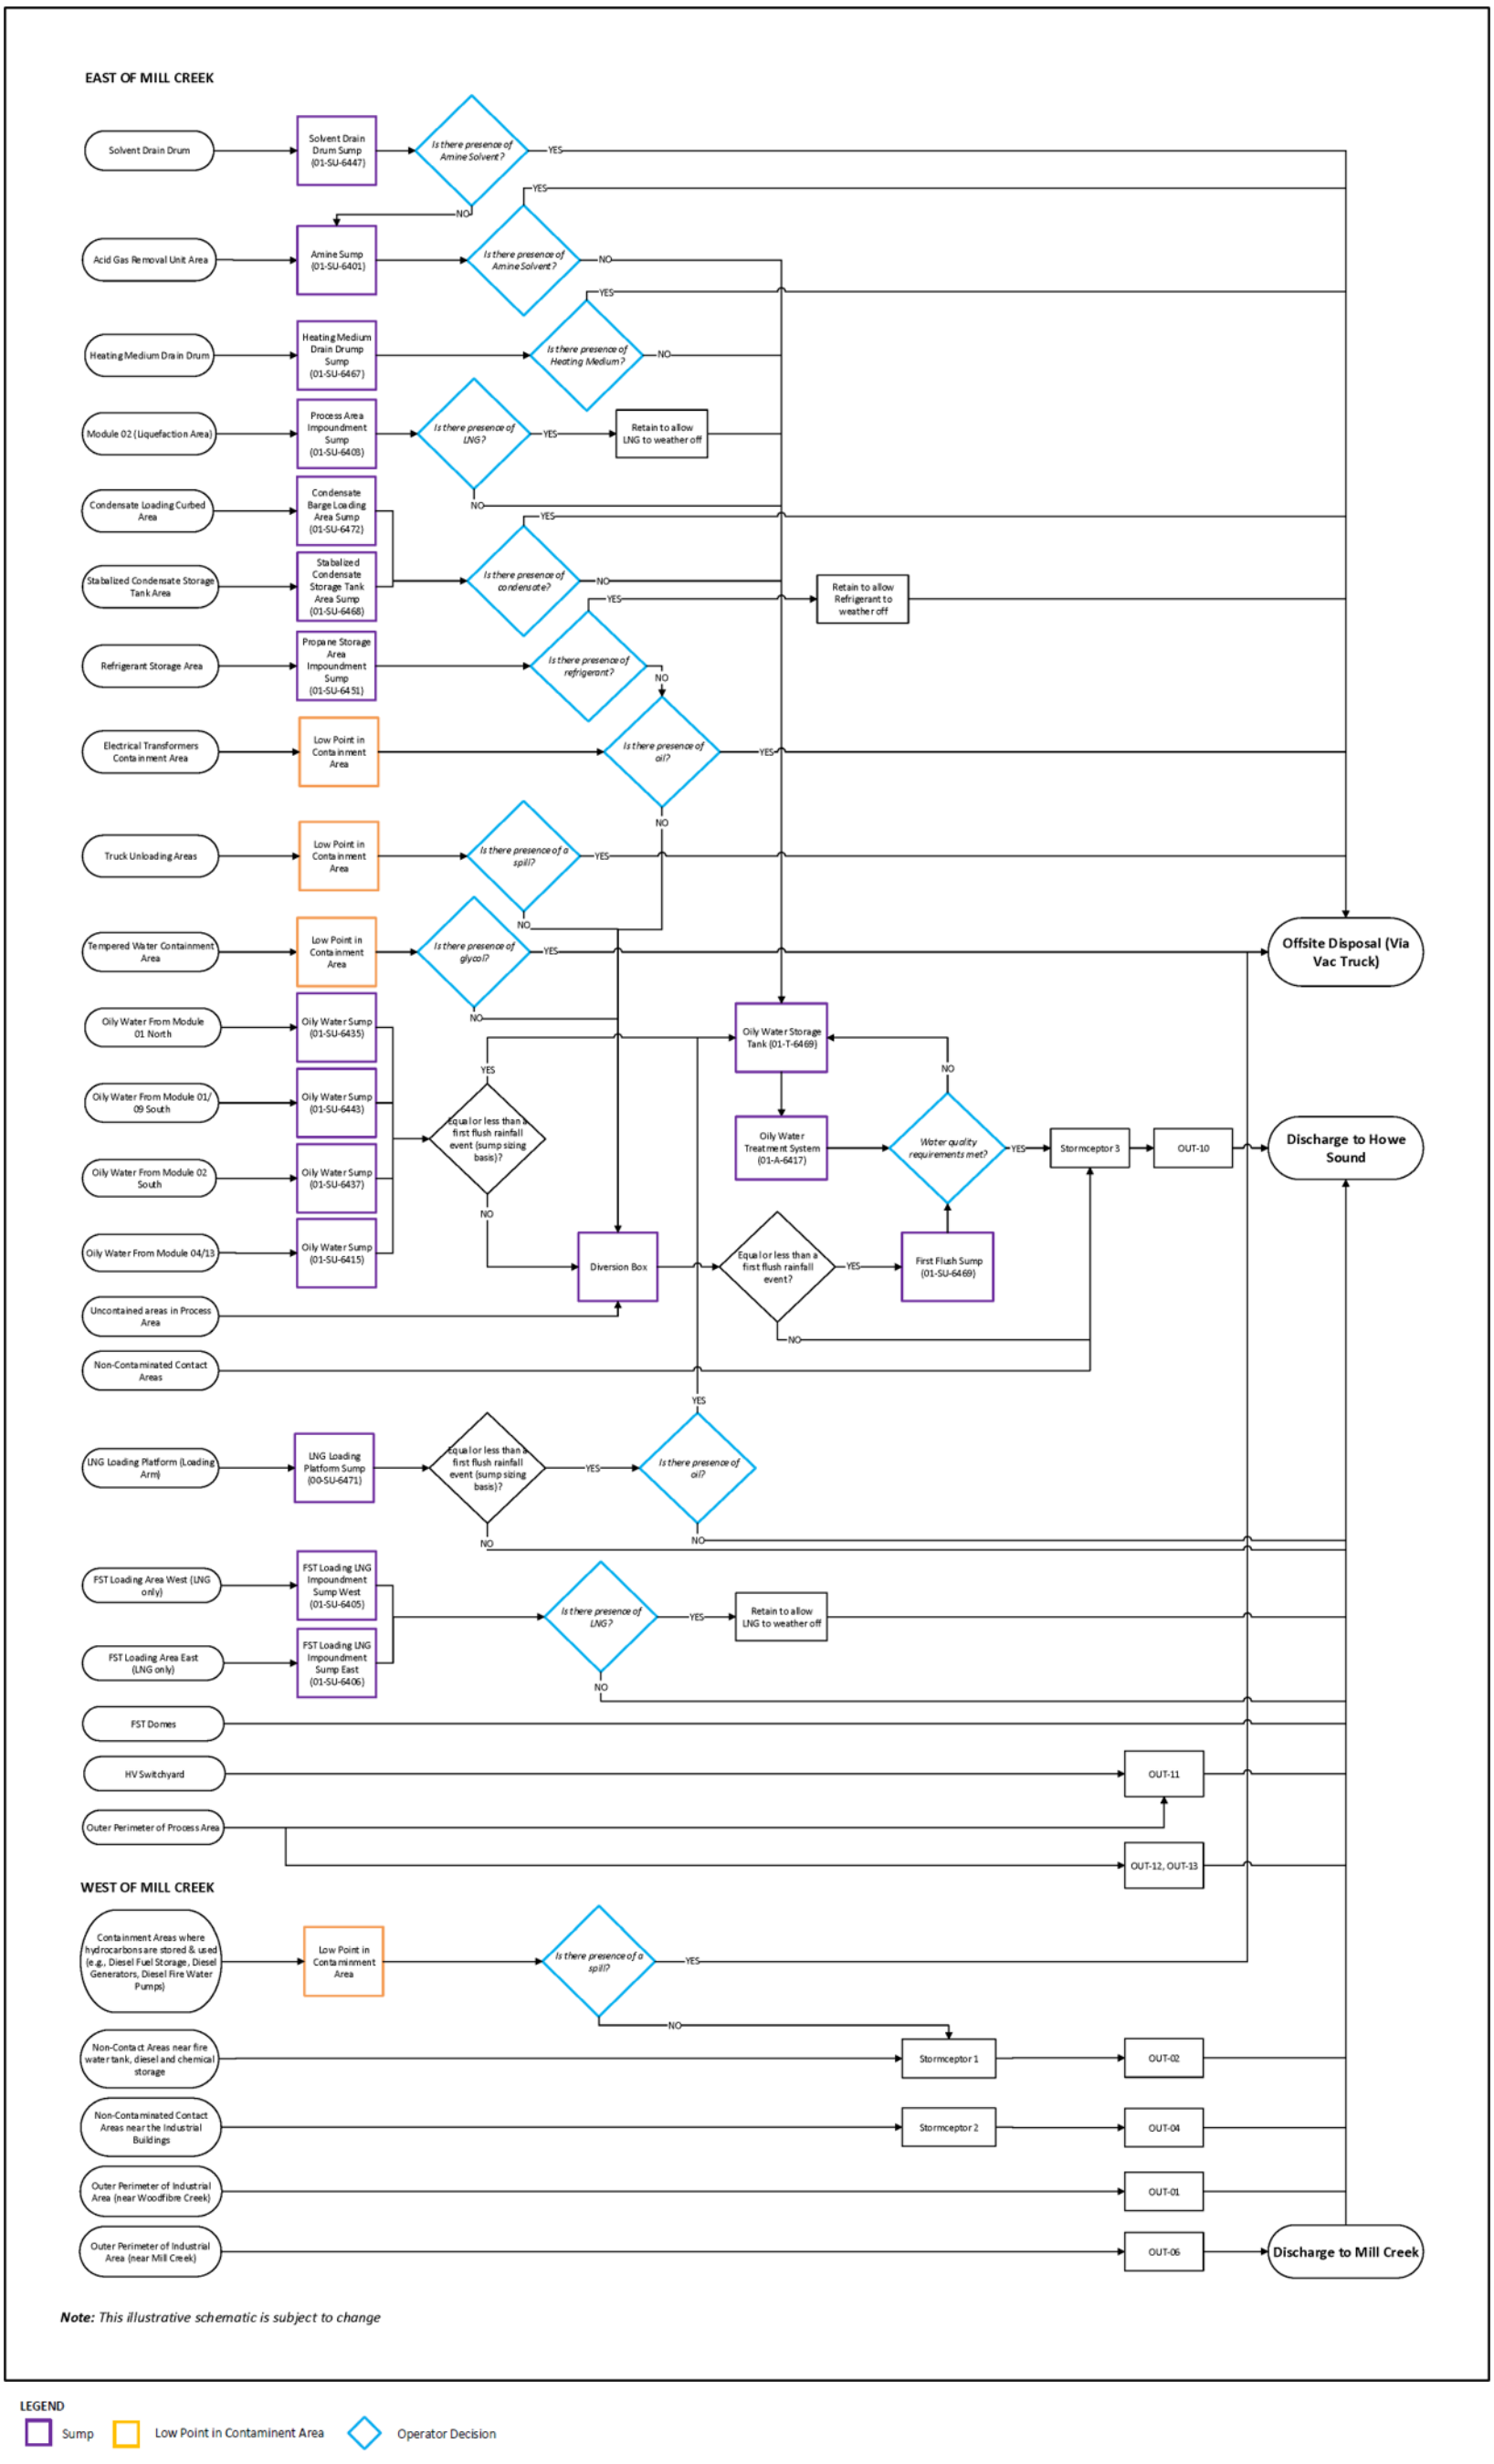

Figure 4-6: Water Management Process Flow Diagram (reproduced from the Operations Stormwater Drainage Management Program [Appendix 4.1-1]).

- **Oily water collection systems:** Designed to intercept drips of lubrication oils from rotating equipment. A system of collection pipes connected to drain drip trays are strategically located at locations where rotating equipment may drip lubrication oil. Stormwater in contact with oily equipment, oily drip collection pipes, and in curbed ground areas drains from the collection system to an Oily Water Sump.
- **Oily Water Sumps:** Located in the LNG Processing Area. Each sump collects drainage from an associated oily water collection system. The sumps will be covered and vented to a safe location and constructed in-ground of reinforced concrete. The oily water sumps are sized to accommodate the first 25 mm of runoff within the potentially contaminated area. Each sump is equipped with an under-weir designed to retain oily water and pneumatic sump pumps, each with a design flow rate of 5 m^3/h. The contents of the oily water sumps (up to the first 25 mm of rainfall) are pumped to the Oily Water Storage Tank:
    - Module 01 North Oily Water Sump (01-SU-6435);
    - Module 01/09 South Oily Water Sump (01-SU-6443);
    - Module 02 South Oily Water Sump (01-SU-6437); and
    - Module 04/13 Oily Water Sump (01-SU-6415).

  During larger rainfall events, stormwater in excess of the first flush rainfall (after the first 25 mm of rain) will discharge through an under-weir configuration into the potentially contaminated contact water system (Section 4.1.5.2).
- **Amine Sump and Containment Area**: Located at the Acid Gas Removal Unit (Module 01) where the amine solvent (OASE Purple) is used. The Amine Sump (01-SU-6401) is an in-ground reinforced concrete sump with the inner walls impermeable to the amine solvent. The oily water collection system for equipment that contains amine, as well as the truck unloading area and the containment area under amine-containing equipment, drain to this sump. The Solvent Drain Drum Sump is also pumped to the Amine Sump. The sump is sized to contain a 100-year, 24-hour storm event to allow for adequate storage if the water is contaminated with amine (for off-site disposal); otherwise, the sump is pumped to the Oily Water Storage Tank.
- **Solvent Drain Drum Sump:** Located at the Acid Gas Removal Unit (Module 01) where the amine solvent (OASE Purple) is used. Potential leaks of amine from equipment are collected by a closed drain system that gravity drains to the Solvent Drain Drum. The sump (01-SU-6447) provides secondary containment for the drum. The amine collected in the drum is recycled to the Acid Gas Removal Unit.

The sump collects stormwater that contacts amine-containing equipment. If the sump contains amine when it is at a high level, it will be emptied by vacuum truck for off-site disposal; otherwise, it will be pumped to the Amine Sump.

- **Heating Medium Drain Drum Sump:** Heating medium (Dowtherm Q) is distributed from the utilities module (M09). Potential leaks of heating medium are collected by a closed drain system that gravity drains to the Heating Medium Drain Drum, for which the sump (01-SU-6467) provides secondary containment. If the sump is at a high level and contains heating medium, it will be emptied by vacuum truck for off site disposal; otherwise, it will be pumped to the Oily Water Storage Tank.
- **Process Area Impoundment Sump:** The sump (01-SU-6405) is designed to contain the 10-year return 24-hour rainfall of 187.1 mm (359 m^3). Stormwater runoff from the LNG containment areas in Module 01 and Module 02 (Figure 4-4) accumulates in the sump and may contain oil from potentially contaminated areas. If oil is observed, the water will be pumped to the Oily Water Storage Tank. If LNG is present, it will be dispersed by evaporation. Runoff volumes exceeding the 10-year, 24-hour storm event will overflow by gravity through an under-weir configuration into the potentially contaminated contact water system (Section 4.1.5.2).
- **Stabilized Condensate Storage Tank Oily Water Sump:** The sump (01-SU-6468) collects drainage from an oily water collection system and stormwater runoff from the condensate storage containment area. If the sump is at a high level and contains condensate, it will be emptied by vacuum truck for off site disposal; otherwise, it will be pumped to the Oily Water Storage Tank.
- **Stabilized Condensate Barge Loading Area Sump:** The sump (01-SU-6472) collects condensate spills and stormwater runoff from the loading spill containment area drainage. If the sump is at a high level and contains condensate, it will be emptied by vacuum truck for off site disposal; otherwise, it transferred by vacuum truck to the Oily Water Storage Tank.
- **Propane Storage Area Impoundment Sump:** The propane (refrigerant) impoundment area drains to this sump (01-SU-6451). Stormwater will collect in the sump. When it reaches a high level, it will be evaluated for the presence of refrigerant or oil. If none are present, the sump will drain to the non-contaminated contact water ditch. Otherwise, it will be transferred to the Oily Water Storage Tank.

- **LNG Loading Platform Sump:** The LNG Loading Platform Sump (00-SU-6471) collects LNG leaks and spills from the associated containment area to facilitate safe evaporation and prevent discharge to Howe Sound. Drips and leaks of hydraulic fluid used in the LNG loading arms are also directed to the sump, as well as stormwater runoff from within the containment area. The sump is configured with an isolation valve. If LNG is present, collected water is retained until the LNG has evaporated. After the first flush volume is collected (*i.e.*, 25 mm rainfall) and conveyed to the Oily Water Storage Tank, collected water is discharged through an underflow weir to Howe Sound.
- **Oily Water Storage Tank**: The Oily Water Storage Tank (01-T-6469) has a 444 m^3 capacity and is used as a surge tank to allow for effective operation of the OWTS. The tank is configured with heating coils to maintain temperature, and a skimmer to remove any floating oil for off-site disposal. The contents of the tank are pumped the OWTS with a pump capacity rated for 30 m^3/hr. Further description is provided in Section 4.2.2.1.1.
- **Diesel Fuel Storage Areas**: Secondary containment is used at diesel storage tanks, essential electricity generators, and the fire water pumps to isolate potential leaks and spills from the non-contaminated contact water system in the Industrial Area. Each containment area is sized to contain 110% of the largest fuel storage volume plus the runoff from a 25-year 24-hour storm event. Contaminated water is removed by vacuum truck for off-site disposal.

4.1.5.2 Potentially Contaminated Contact Water System

The potentially contaminated contact water system, located in the LNG Processing Area, manages stormwater that is outside of the contaminated contact water system secondary containment areas and is typically free of POCs and POPCs. A trench drain collection system on the perimeter of the process modules conveys stormwater to the Diversion Box (Figure 4-4). In accordance with industry best practices, the Diversion Box directs the initial stormwater runoff from the first 25 mm of rainfall (i.e., the first flush) to the First Flush Sump. Once the First Flush Sump reaches capacity, the subsequent stormwater is assumed to have limited pollution potential (i.e., it is non-contaminated); therefore, the Diversion Box allows subsequent stormwater runoff to overflow into the non-contaminated contact water system. The contact water stored in the First Flush Sump is directed to the OWTS (if contaminated with oil) or the non-contaminated contact water system (if non-contaminated). Specific components of the potentially contaminated contact water system are described below:

- **First Flush Sump**: The First Flush Sump (01-SU-6469) has a capacity of 500 m^3 and is sized to accommodate the initial 25 mm of stormwater runoff (*i.e.*, the first flush volume) within the potentially contaminated area. The Diversion Box directs the initial 25 mm of runoff to the First Flush Sump where it is held for sampling and testing, followed by further treatment in the OWTS (if EPH is present) or controlled disposal if the water is non-contaminated. Water is pumped out of the sump to the OWTS or to the non-contaminated contact water system using pumps that can achieve a maximum flow of 30 m^3/hr.
- **Tempered Water Containment Area**: The cooling system located in Module 09 contains tempered water (*i.e.*, 40% ethylene glycol). Secondary containment surrounds the area under equipment that contains tempered water and is sloped towards a low point with normally closed isolation valves. Accumulated stormwater that contains glycol will be removed by a vacuum truck for offsite disposal; otherwise, the contact water will be allowed to drain to the non-contaminated contact water system.
- **Electrical Transformer Containment Areas**: Electrical transformers are located in curbed containment areas (sized to contain 110% of the dielectric oil within the largest transformer) that slope to a low point with normally closed isolation valves. Accumulated water that does not contain oil will be released to the non-contaminated contact water system via the manual valve. Contaminated water is removed by vacuum truck for off-site disposal or is transferred to the Oily Water Storage Tank.
- **Oily Water Storage Tank Containment Area**: The secondary containment for Oily Water Storage Tank and OWTS is bounded on three sides by trenches that drain to a low point that is configured with an isolation valve. If oil is observed in the contained water, the water will be transferred to the Oily Water Storage Tank; otherwise, the valve will be opened to drain the water to the potentially contaminated water system.

4.1.5.3 Non-contaminated Contact Water Systems

The non-contaminated contact water systems are located in contact water management areas outside of areas where facility leaks or spills may occur. These areas encompass the Industrial Area west of Mill Creek, areas east of Mill Creek outside of the LNG Processing Area and the Refrigerant and Condensate Storage Area, as well as the Marine Terminal Area. East of Mill Creek, stormwater from uncontained paved and unpaved non-contaminated areas will flow by gravity as sheet flow into open drainage ditches. West of Mill Creek, stormwater from non-contaminated and uncontained paved and unpaved areas,

including buildings, will be conveyed by gravity to concrete trenches, lined riprap ditches, or catch basins connected to a storm sewer network. All runoff is conveyed through a Stormceptor (*i.e.,* hydrodynamic oil/grit separator) before discharging to Howe Sound through outfalls OUT-02, OUT-04 and OUT-10. The layout of the non-contaminated contact water systems east and west of Mill Creek is shown in Figure 4-4 and Figure 4-5, respectively. Additional information on the land-based system is provided below:

- **Erosion Controls:** Non-contaminated area surfacing is completed using low-fines compacted gravels on level surfaces, rip-rap or vegetation on slopes. Frequently trafficked areas are paved with asphalt or concrete. Non-contaminated water passes through Stormceptor oil/grit separators prior to discharge.
- **Collection Ditches:** Ditches are sized for the 100-year return period rainfall event, are trapezoidal in shape with slopes of 2 to 1 (or flatter), and are lined with rip-rap to provide erosion protection and sediment control. There are also vertical-wall concrete trenches with grating covers in areas where space constraints prevent installation of a trapezoidal ditch.
- **Culverts and Outfalls**: Culverts are sized to convey the 100-year return period rainfall event. The minimum invert elevation of all outfall culverts is 2.0 m (above the 1.95 m Higher High-Water Level – Large Tide in the Squamish area) to maintain conveyance capacity during high tide periods.
- **Stormceptors**: The use of a Stormceptor is best practice for the management of stormwater from industrial settings. Therefore, non-contaminated contact water is routed through Stormceptors prior to discharge into Howe Sound. Stormceptors are equipped with oil/grit separators to remove sediments and surficial oil from smaller but more frequent rainfall events (Figure 4-7). The lower basin collects TSS, and oils are trapped by the weir and insert.

The Marine Terminal Area contains the FSTs and the FST Loading Area platform (Modules 05A and 05B). The uncontained areas on these facilities are not associated with hydrocarbon-handling equipment or contamination sources and stormwater discharges directly to Howe Sound. Contained areas include the LNG Loading Platform Sump (managed as described in Section 4.1.5.1), East and West FST Loading Area LNG Impoundment Sumps (01-SU-6405 and 01-SU-6406, respectively), and LNG Containment Platforms used for the FST manifolds, storage tanks and marine topsides. The containment facilities allow for evaporation of LNG prior to discharge of any contact water that has accumulated in the sumps to Howe Sound.

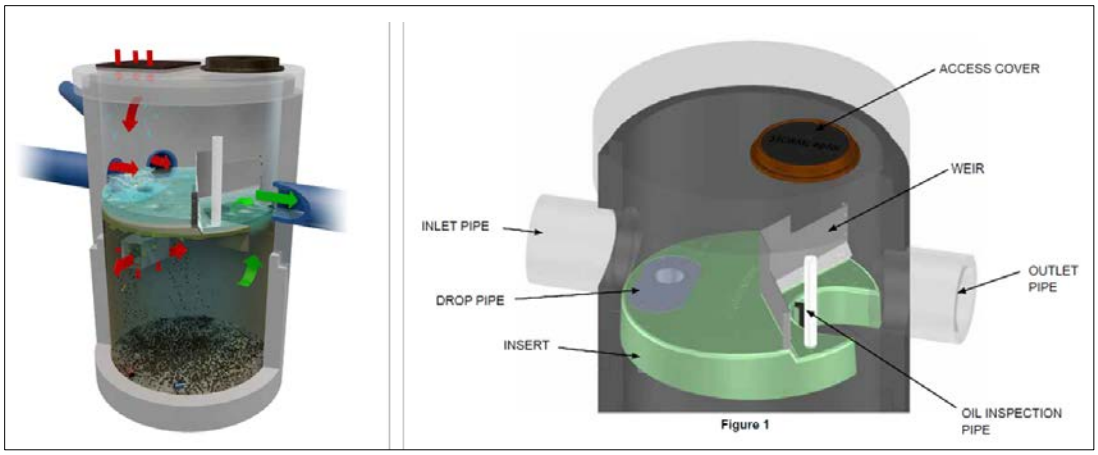

Figure 4-7: Stormceptor Oil-Grit Separator Operational Schematic

4.1.6 Trigger and Response Plan

The trigger and response procedures establish threshold values that trigger follow-up actions if monitoring data indicate a parameter concentration is approaching a WDA discharge limit. Threshold concentration values are established for OUT-10 discharge to Howe Sound in the SWDMP (Section 6.0 of Appendix 4.1-1). Field turbidity measurements will be used to estimate TSS concentrations for real-time evaluation of effluent quality, whereas laboratory test results will be evaluated upon receipt. The water quality results will be compared to threshold values that are set at 80% and 95% of the discharge limits specified in the WDA. If a threshold value is exceeded, the appropriate actions will be initiated to investigate and mitigate the concentration of a parameter that is above a threshold value. The typical actions described in the SWDMP (Appendix 4.1-1) are reproduced in Table 4-5 and Table 4-6 below.

Table 4-5:
Field Monitoring Management Trigger and Action Response Plan (reproduced from the Operations Stormwater Drainage Management Program [Appendix 4.1-1])

Response Level	Basis	Notification	Action
Level 1	Turbidity ≥80% of the WDA limit for TSS	Environment Manager (or approved designate)	• Repeat field measurement to verify value. • Investigate the potential source(s) contributing to the elevated measurement (*e.g.*, review of the monitoring data from outlet of the OWTS and undertake further monitoring at the First Flush Sump if warranted). • Identify and implement mitigation actions if there is potential for the concentration of the parameter to continue to increase. • Increase the monitoring frequency at OUT-10 until exceedance of WDA limits are no longer a concern (to be defined based on the potential source(s) and mitigation measures being implemented).
Level 2	Turbidity ≥95% of the WDA Limit for TSS	Environment Manager and Operations Manager	• Level 1 activities. • Implement contingency planning (where applicable) to cease or minimize discharge to Howe Sounds until there is a reduction in turbidity levels.

Table 4-6:
Laboratory Monitoring Management Trigger and Action Response Plan (reproduced from the Operations Stormwater Drainage Management Program [Appendix 4.1-1])

Response Level	Basis	Notification	Action
Level 1	80% of WDA limit for parameters with discharge limits	Environment Manager (or approved designate)	• Review laboratory certificate Quality Assurance/Quality Control (QA/QC) reports. Validate original result, or re-run sample within 24 hours if a laboratory error was identified. • Undertake confirmatory monitoring / sampling. • Investigate the potential source(s) contributing to the elevated parameters (*e.g.*, review the turbidity measurements, assess the OWTS). • Identify and implement mitigation actions if there is potential for the concentration of the parameter to continue to increase. • Increase the monitoring frequency at OUT-10 until exceedance of WDA limits are no longer a concern (to be defined based on the potential source(s) and mitigation measures being implemented).
Level 2	95% of WDA limit for parameters with discharge limits	Environment Manager and Operations Manager	• Level 1 activities. • Implement contingency planning (where applicable) to cease or minimize discharge to Howe Sounds until verification that the mitigation measures are addressing the elevated parameter concentrations. • If the event has potential to exceed permit limits, engage with a qualified professional (QP) for the evaluation of potential effects to aquatic resources, which will support non-compliance notifications to the BCER (if triggered).

4.1.7 Adaptive Management Plan

The adaptive management plan (Section 7.0 of Appendix 4.1-1) describes the approach for reducing uncertainty regarding the expected concentrations of POPCs and POCs in effluents that are discharged from the Project site. The adaptive management approach is an iterative process that includes problem assessment, planning, implementation of management actions, monitoring, evaluation and adjustment, with the cycle repeating until the identified uncertainties are sufficiently reduced. The contact water management system is designed to address the uncertainties for POPCs and POCs in effluents.

During operation of the Project, effluent quality and receiving environment water quality will be monitored. If the monitoring results indicate elevated uncertainty regarding the control of POCs and POPCs in Project effluents that cannot be addressed through operational adjustments, the adaptive management process will be initiated following the framework described in the SWDMP (Appendix 4.1-1) and the technical guidance provided in Development and Use of Adaptive Management Plans (ENV, 2022).

4.1.8 Contingency Plan

Contingency plans have been prepared for operational situations that interfere with the normal operation of one or more components of the water management system (Section 4.0 of Appendix 4.1-1). The contingency plans are designed to prevent the discharge of non-compliant effluent. A variety of scenarios are identified with examples of typical management responses. The situations that are addressed include power outages, blockages in the contaminated water collection system, equipment failure, and operator error. The contingency plans are presented in Table 4-7.

Table 4-7:
Contingency Scenarios and Management Actions (reproduced from the Operations Stormwater Drainage Management Program [Appendix 4.1-1])

Scenario	Management Actions
Contaminated Contact Water System	
Failure of the OWTS (due to equipment failure, power failure, blockages, unable to maintain minimal operating temperature, failure of flow meter *etc.*), therefore unable to remove the free and dispersed oil and settleable and suspended solids in the stormwater drainage effluent collected in the Oily Water Storage Tank.	• The discharge from the Oily Water Storage Tank to the OWTS will be stopped. • The effluent within the OWTS will either remain within the system (pending the type of failure) or be pumped back to the Oily Water Storage Tank if there is capacity. • When nearing the capacity of the Oily Water Storage Tank, the water will be pumped into temporary storage containers and either temporarily stored on site and/or sent offsite for disposal.
Failure of both oil in water (*i.e.*, EPH) analyzers in the OWTS therefore unable to verify if the discharge water meets the specification.	• Effluent will be recirculated back to the Oily Water Storage Tank, on the basis that if the water quality can not be verified, the effluent is deemed as not meeting the discharge specification.
Influent from the Oily Water Storage Tank exceeds the design specification for total suspended solids and/or free and dispersed oil (*i.e.*, EPH).	• Treatment process will continue; the effluent will be recirculated back to the Oily Water Storage Tank if it does not meet the discharge specification.
Failure of both inlet feed pumps (*i.e.*, the one in service and the spare failures) preventing discharge into the OWTS.	• Repair one of the two inlet feed pumps if possible, pending the failure. • Temporary pump solutions will be evaluated to pump the oily water from the Oily Water Storage Tank to the OWTS if one inlet feed pump cannot be brought back online in the timeframe needed to manage the water level within the Oily Water Storage Tank.
Oily Water Storage Tank overfills; resulting in the loss of containment and release of oily water to the contained area around the Oily Water Storage Tank.	• The released oily water would flow to the low spot within the containment area. • Internal incident event process will be triggered to manage the spill and undertake the required actions for reporting and cleanup.
Failure of a sump pump / level indicator in the contaminated contact water, resulting in the stormwater drainage being unable to be pumped to the Oily Water Storage Tank.	• The failed pump will be replaced by a spare pump (common warehouse spares are available for the 5 and 30 m^3/hr pumps). • Any excess oily water will remain within the containment area and subsequently be removed using the spare pump. • If required, the operator will use a vacuum truck to transfer the oily water from the sump to the Oily Water Storage Tank or offsite for disposal (pending quality).
Errors in the management of the amine sump, resulting in amine solvent being pumped to the Oily Water Storage Tank.	• Oily Water Storage Tank will be emptied using a vacuum truck and the contents disposed offsite at an approved facility after sampling has been completed.
Potentially Contaminated Contact Water System	
Failure in the First Flush Oily Water Sump Pump at the First Flush Sump, preventing the routing of the stormwater back to the Oily Water Storage Tank.	• The failed pump will be replaced by a spare pump (common warehouse spares are available for the 30 m^3/hr pumps). • If required, the operator will use a vacuum truck to transfer the oily water from the sump to the Oily Water Storage Tank or offsite for disposal (pending quality).
Errors in the management of the Tempered Cooling Water secondary containment area, resulting in glycol being pumped to the First Flush Sump.	• Effected chamber(s) of the First Flush Sump will be emptied using a vacuum truck and the contents disposed off site at an approved facility after sampling has been completed.

4.1.9 Episode Management Plan

Management plans for addressing environmental episodes such as spills, fire and flooding that may affect the performance or operation of the water management system are outlined in the SWDMP (Section 5.0 of Appendix 4.1-1). The plans for managing fires and floods will be described in the Emergency Response Program for the Project and will outline the operation of the water management system under those circumstances.

The water management system is designed to monitor for and contain spills of reagents and petroleum hydrocarbons. All spills will be contained, cleaned up and disposed of appropriately. Appropriate measures will be implemented to prevent or minimize the release of POCs and POPCs to contact water and to the terrestrial and aquatic receiving environments. Outside agencies will be notified in accordance with the operations WDA Effluent Permit, regulatory, and legal requirements. First Nations will be notified if a spill may or does enter the terrestrial or aquatic receiving environment.

4.1.10 Implementation Plan for Operations Water Management

As the Project construction nears completion, it will be necessary to commission and implement the operations water management program. Temporary infrastructure used solely to support construction activities are forecast to commence being systematically decommissioned in the second half of 2027 once no longer required for site water management, including the backfilling of the sedimentation ponds and demobilization of the construction wastewater treatment plants.

The construction contact water management program is designed to manage POPCs originating from historical soil contamination at the Project site, as well as elevated levels of TSS that are associated with construction activities (*e.g.,* site excavations and development). The operations water management program reflects the final completed configuration of the Project and the management of POPCs and POCs that are associated with LNG facility operation. This section outlines how the water management and monitoring programs will transition from the construction program to the operations program during commissioning of the Project.

4.1.10.1 Overview of Construction Water Management

The construction contact water management system for the Project is designed to manage TSS and other contaminants that are associated with civil works such as ground excavation, fill placement, concrete production and pouring, and installation of finished surfaces. The discharge of construction contact water to Howe Sound is regulated by WDA Effluent Permit PE-111578. The principal facilities for construction phase water management in use

as of April 2026 are shown in Figure 4-8 (at the end of Section 4.1.10.2). Non-contact water is intercepted and diverted around the construction areas to Howe Sound and Mill Creek. Stormwater runoff collected within the east and west catchment areas (7.12 and 5.92 ha, respectively) is managed as site contact water using a system of temporary berms, ditches, sumps and baker tanks for intermediate storage. The location of these facilities is adjusted as construction progresses. Water from potentially contaminated areas is conveyed to the East Wastewater Treatment Plant (WWTP) for treatment, whereas water from non-contaminated areas is directed to the East or West Sedimentation Ponds for settling of TSS prior to discharge.

Discharge from the East and West Sedimentation Ponds is controlled using pumps. Each of the ponds is configured to discharge to either OUT-04 (SP-W-OUT, West Sedimentation Pond) or OUT-10 (SP-E-OUT, East Sedimentation Pond). However, since mid-2025, all sedimentation pond effluent is pumped to a TSS settling system which uses sand filters to remove TSS prior to discharge to Howe Sound through OUT-04 (SP-W-OUT). The TSS settling system consists of six parallel treatment trains, each with an installed capacity of 2,450 m^3/day (yielding an overall capacity of 14,700 m^3/day) that is designed to process stormwater flows associated with a 24 hour 2-year return period storm event. Construction effluent discharge is associated with rainy periods and storm events and generally does not occur during dry periods, except for discharges associated with pond maintenance.

4.1.10.2 Transition to Operations Water Management

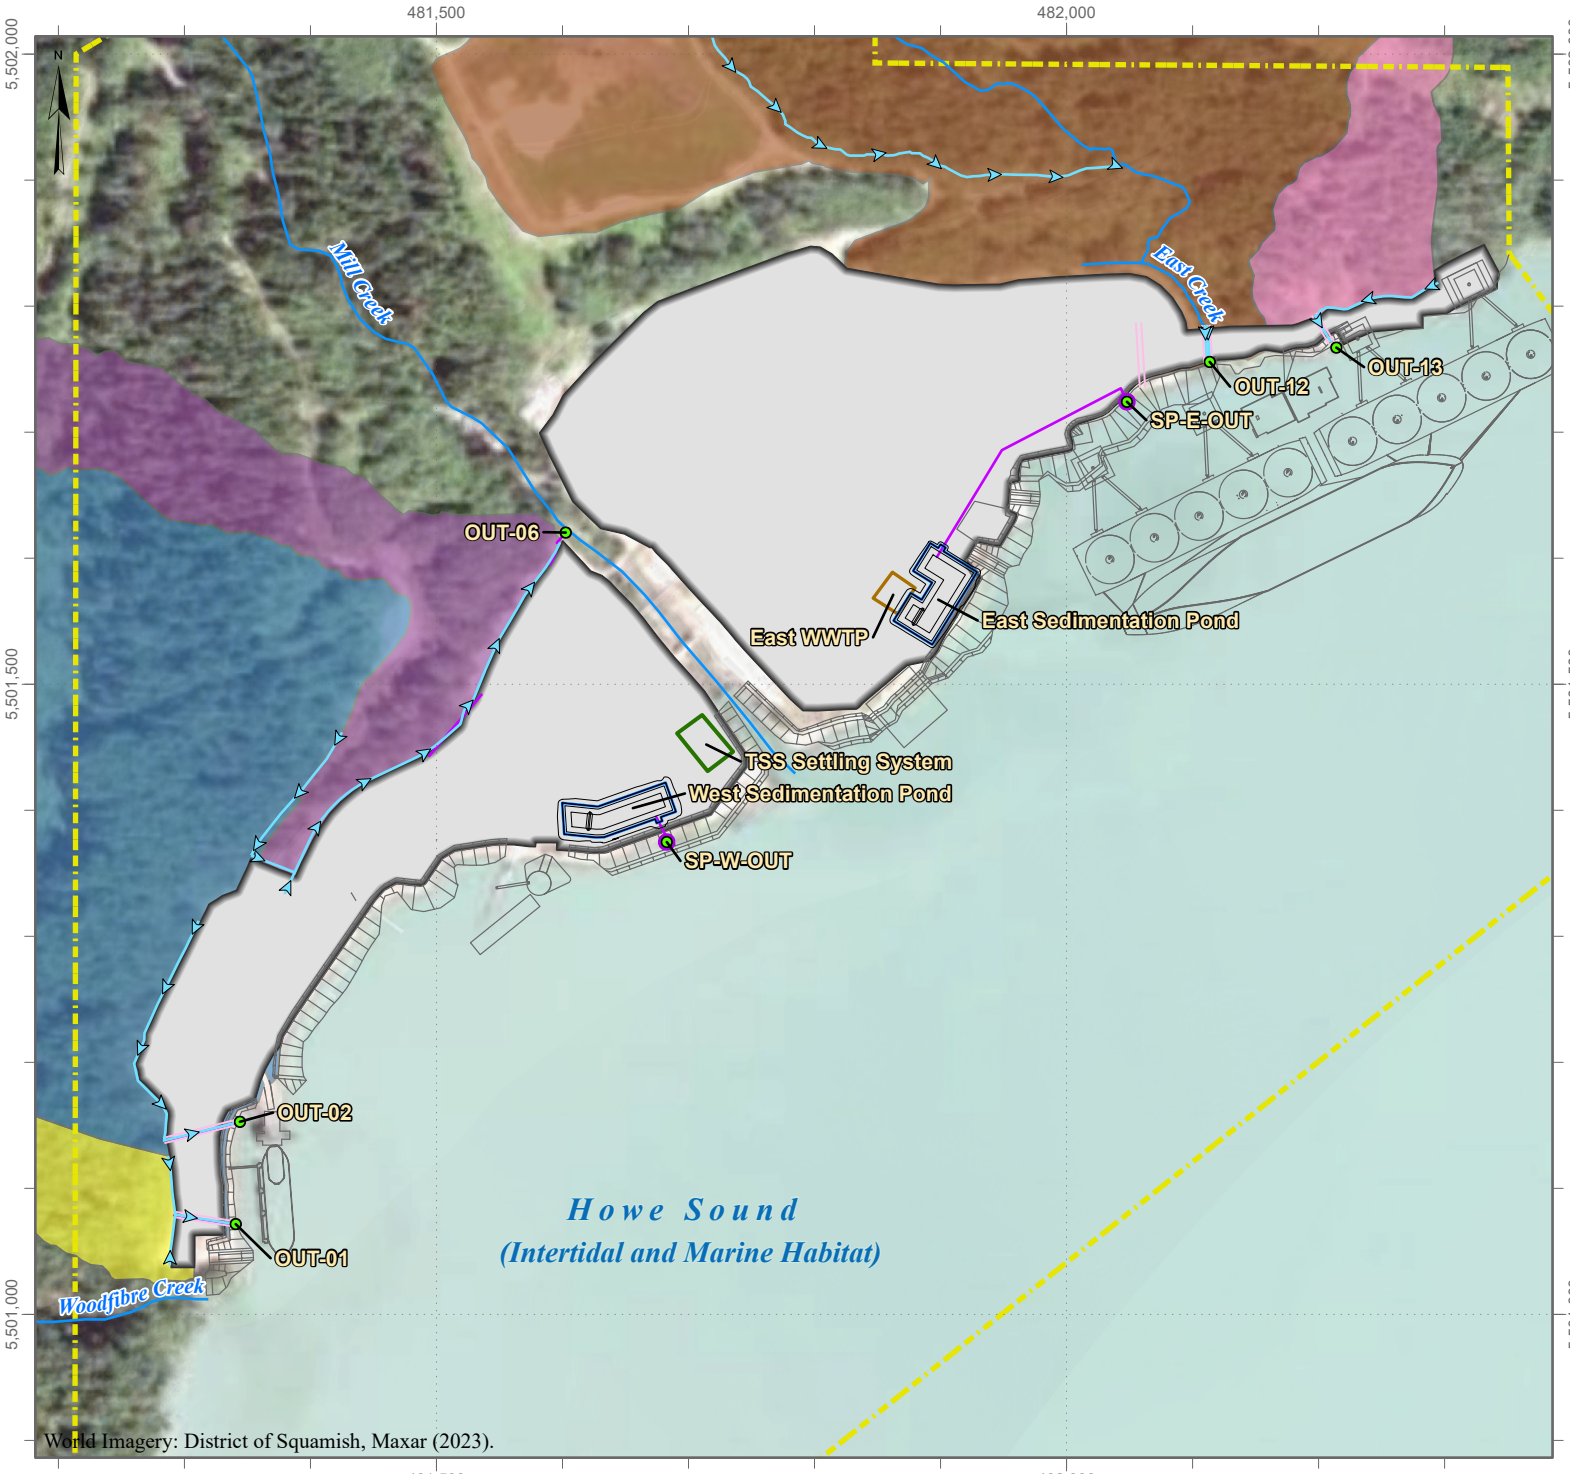
The water management infrastructure for operations is being upgraded or installed during construction. Sub-areas of the Project site will transition from temporary (*i.e.,* construction) to the permanent (*i.e.,* operations) water management facilities as components of the operations water management infrastructure are commissioned (refer to Section 4.1.10.3) and final grades and surfacing are completed. In general, drainage from these sub-areas will continue to be managed by the construction water management system until ground preparations are completed and the only remaining site preparation tasks are to decommission the construction sedimentation ponds and associated treatment systems. The transition of any drainage catchment to the permanent operational stormwater management system shall require documented verification that:

- temporary construction drainage controls are no longer required for the applicable area;
- permanent drainage infrastructure is mechanically complete and operational;
- sump pumps, level instrumentation, oil-in-water analyzers, diversion valves, alarms, and communications have been functionally tested;

- temporary construction-related sediment or contamination sources have been removed or isolated;
- associated commissioning activities have been reviewed for potential wastewater impacts; and
- discharge routing and contingency measures have been confirmed.

The initial operations drainage system sub-areas forecast to be ready for use by the end of Q2 2027 are non-contact and non-contaminated contact water catchments on the periphery of the site (OUT-01, OUT-02, OUT-06 and OUT-13), the East Creek outlet (OUT-12), the LNG Processing Area, the Refrigerant and Condensate Area, and inland portions of the Industrial Area. Runoff from non-contact and non-contaminated contact water catchments will drain to each outlet as shown in Figure 4-9. Runoff from potentially contaminated and contaminated areas that are discharged through SP-W-OUT and SP-E-OUT will continue to be managed under construction WDA Effluent Permit PE-111578 as described below:

- Secondary containment will be implemented in the LNG Processing Area to isolate potentially contaminated water. Temporary pumps will be installed in the Amine Sump and LNG Processing Area Sump. If water in the sumps and contained areas is non-contaminated (as confirmed by testing), it will be pumped to the potentially contaminated contact water collection trench; otherwise, it will be collected by vacuum truck for off-site disposal. The First Flush Sump will receive drainage runoff from the potentially contaminated contact water collection trench. If the water in the sump is non-contaminated (as confirmed by testing), a temporary pump will direct the water to the East Sedimentation Pond; otherwise, it will be collected by vacuum truck for off-site disposal. Any areas not completed shall have full secondary temporary containment installed until the entire system has been completed.
- Drainage from the contaminated contact water collection system (*i.e.*, oily water collection system) will accumulate in the Oily Water Storage Tank. If the water only contains oil (as confirmed by testing), it may be treated using the OWTS, otherwise it will be collected by vacuum truck for off-site disposal. OWTS treated water will be directed to the East Sedimentation Pond.
- The Refrigerant and Condensate Area sumps will be configured with temporary pumps. Not-contaminated water (as confirmed by testing) will be pumped to the East Sedimentation Pond.
- The sub-areas of the Industrial Area shown in Figure 4-9 are considered non-contaminated areas. Stormwater runoff from these areas will be directed to the West Sedimentation Pond.



- The OWTS is scheduled to be commissioned for use in Q2 2027 (refer to Section 4.2.7). Treated effluent from the OWTS that meets minimum discharge objectives (MDOs) will be directed to the East WWTP.

The Industrial Area water management facilities are planned to be ready for use in Q3 2027. This will include installation of Stormceptors STC-01 and STC-02, connection of associated piping, final grading collection ditches, and completion of asphalt and gravel final surfacing. The current approach is to first complete the OUT-02 non-contaminated contact water catchment area, and then progress to the OUT-04 non-contaminated catchment area (subject to change as construction progresses). Construction water management will be implemented until each area is completed, at which point the West Sedimentation Pond will be backfilled and the TSS Settling System will be subsequently demobilized. Daily field and weekly analytical monitoring will be initiated at OUT-02 and OUT-04 after the operations non-contaminated contact water systems are commissioned for these outlets. This will be conducted under construction WDA PE-111578 and transitioned to the operations WDA once it comes into effect. The configuration of the water management system, as anticipated for the end of August 2027, is shown in Figure 4-10.

The operations water management system east of Mill Creek is planned to be ready for use by end of Q3 2027. Non-contaminated contact water will be directed to the East Sedimentation Pond, and clarified effluent will be discharged at SP-E-OUT (as shown in Figure 4-9) while construction activities are being executed. Similar to the Industrial Area, completion will include installation of Stormceptor STC-03 and associated connections to ditches and the OUT-10 (SP-W-OUT) outfall structure. Final grading of the ditch from the MOF to STC-03 will be completed, as well as final gravel surfacing of the remaining areas. The West Sedimentation Pond will then be emptied and backfilled, and the East WWTP will be decommissioned and removed from site. After the East WWTP is decommissioned and the operations water conveyance systems are connected to OUT-10, it is recommended that the operations WDA come into effect. Daily field and weekly analytical monitoring will be initiated at OUT-10 when it is connected to the operations water conveyance systems. The water management configuration forecast for the end of Q3 2027 is shown in Figure 4-11.

During periods of overlapping construction and operational activities, temporary isolation, diversion, or containment measures may be implemented to prevent construction-related wastewater from entering the permanent operational drainage system.

Under no circumstance shall untreated construction wastewater or known off-specification commissioning effluent be intentionally discharged through the operational OWTS discharge pathway to Howe Sound.

4.1.10.3 Equipment Commissioning Protocols

The permanent (operations) stormwater management systems are planned to be commissioned and put into service ahead of the overall LNG facility commencing operations, and prior to the completion of construction activities. There will also be commissioning activities associated with the LNG equipment that will have an interface with the permanent stormwater management systems in service.

After equipment is verified to be mechanically complete, there are pre-commissioning and commissioning activities undertaken to test the systems before they obtain the status "ready for start up" and are subsequently put into operations. The intent is that the permanent stormwater management systems within each module/area will have completed commissioning activities prior to the LNG equipment and piping in that area being commissioned and prior to the commissioning of the OWTS (refer to Section 4.2.7).

Commissioning activities associated with systems connected to the permanent stormwater management and OWTS shall be executed under formal commissioning system boundaries and permit-to-work controls. Prior to introduction of hydrocarbons, chemicals, lubricants, or process fluids into a system, the applicable drainage collection systems, containment systems, sump pumps, monitoring instrumentation, diversion valves, and temporary containment measures shall be verified as operational and available for service.

During commissioning, any wastewater generated from flushing, cleaning, degreasing, hydrotesting additives, lubrication oil flushing, chemical cleaning, glycol systems, or other non-routine commissioning activities shall be segregated from the permanent stormwater drainage system unless specifically assessed and approved for treatment through the OWTS.

Formal handover of the permanent water management systems from construction to operations shall occur only after completion of:

- mechanical completion;
- pre-commissioning activities;
- functional testing;
- cause and effect verification;
- instrument calibration;
- diversion logic testing; and
- commissioning acceptance testing in accordance with approved procedures.

Commissioning activities for the permanent stormwater system include verification that the sumps and collection ditches are free of debris, and sump pumps, valves and associated instrumentation are performing correctly. Therefore, during commissioning of the permanent system, stormwater runoff in these areas will be managed in accordance with construction WDA Effluent Permit PE-111578, as described in Section 4.1.10.2.

The effluent generated from the commissioning of the OWTS will be routed back to the Oily Water Storage Tank if not in compliance with the operations WDA Effluent Permit discharge limits (refer to Section 6).

During commissioning of the equipment and piping in the LNG Processing Area, a range of commissioning fluids will be used, generated, and disposed. Examples include the lube oil flushing of all of the compressors (located in several modules) and the de-greasing of the acid gas removal unit in M01 using a mild detergent (*e.g.*, soda ash). Both of these activities will be performed as closed loop activities, with all fluids/detergent collected and removed from the site for appropriate disposal. Temporary bunds may be used to collect any potential leaks; otherwise, the leaks will be confined within the drainage sumps in those areas. Vacuum trucks will be used to removed accumulated fluids for off-site disposal at an appropriate facility.

4.2 Wastewater Treatment System

As described previously, an OWTS is proposed to provide treatment for contaminated and potentially contaminated contact water for operations. The purpose of the OWTS is to treat contaminated or potentially contaminated contact water to the established discharge criteria (Section 4.2.1.3).

This section includes a summary of the OWTS Best Available Technology Assessment (BATA), design basis, design criteria, treatment effectiveness, performance risks, operation and maintenance requirements, performance testing, estimated capital and operating costs, and the commissioning schedule. The information presented herein has relied upon documentation prepared for WLNG by the OWTS vendor, Cannon Artes, and McDermott, including the *Operations Phase Best Achievable Technology Assessment (BATA)* (MDR, 2026b; Appendix 4.2-1) and the *Unit 64 Effluent and Wastewater System – Process Design Basis* (MDR, 2025c; Appendix 4.2-2).

4.2.1 Best Achievable Technology Assessment

A BATA was completed by McDermott (MDR, 2026b; Appendix 4.2-1). The objective of the BATA is to select the best treatment approach for addressing all contaminated or potentially contaminated water such that only treated water which meets discharge

objectives is discharged into Howe Sound through the non-contaminated contact water system (Section 4.1.5.3). The following sections summarize the identified contamination sources and management approaches (Section 4.2.1.1), design basis (Section 4.2.1.2), and minimum discharge objectives (MDOs) (Section 4.2.1.3), as described in the BATA report (MDR, 2026b; Appendix 4.2-1).

4.2.1.1 Contamination Sources and Management Approach

The OWTS was selected based on expected POCs and POPCs that are listed in Table 4-2 (in Section 4.1.2). The BATA included an evaluation of feasible management options for each source of contaminated or potentially contaminated contact water. The evaluation considered treatment reliability, control-effectiveness and cost-effectiveness, and identified the best treatment approach for each potential contaminant source. Two primary approaches were identified: 1) on-site treatment of contaminated and potentially contaminated stormwater runoff, and 2) off-site disposal of drips, leaks, and spills of POPCs. The source of potential contamination and selected management approach for each POPC is summarized in Table 4-2 (Section 4.1.2).

4.2.1.2 Design Basis

This section presents the estimated OWTS influent volumes (Section 4.2.1.2.1) and quality (Section 4.2.1.2.1) that constitute the design basis for the OWTS.

4.2.1.2.1 Estimated OWTS Influent Volumes

The influent sources for the selected Best Available Technology (BAT) system consist of contaminated and potentially contaminated contact water generated within the facility. Influent volumes are based on historical precipitation data from the Squamish STP Central station (1981–2010), with November's peak average rainfall (391 mm) used as a conservative design basis. A potentially contaminated catchment area of 20,000 m^2 is conservatively assumed, recognizing not all runoff will require treatment. To accommodate peak flows and allow for maintenance, the system is designed for 50% utilization with a 10% contingency, resulting in a minimum required capacity of approximately 24 m^3/h.

4.2.1.2.2 Estimated OWTS Influent Quality

The BATA (MDR, 2026b; Appendix 4.2-1) identified EPH and TSS as the Parameters of Concern (POCs) to carry forward for on-site treatment (Section 4.2.1). The oily water collection system is designed such that any residual oil is contained within the system prior to being conveyed to the BAT treatment system. Precipitation will entrain oil and scour loose particulate from concrete surfaces; however, because most areas will be paved, the overall solids loading is expected to be low.

The following influent concentrations are assumed for the purposes of evaluating the BAT:

- Extractable Petroleum Hydrocarbons (EPH): approximately 50 mg/L; however, the treatment system is specified with an influent concentration of 200 mg/L EPH to provide a conservative operating envelope.
- Total Suspended Solids (TSS): approximately 100 mg/L; however, the treatment system is specified with an influent concentration of 200 mg/L TSS to provide a conservative operating envelope.

These values represent conservative design estimates under normal operating conditions and include allowance for possible, but unexpected, transient increases in EPH and TSS loading.

4.2.1.3 Minimum Discharge Objectives

The purpose of the OWTS is to treat contaminated or potentially contaminated contact water to the established discharge criteria, referred to as minimum discharge objectives (MDOs). MDOs are established for POPCs identified in the BATA based on the most conservative applicable Federal or B.C. water quality guidelines for MWAL, where available. Management strategies were also considered for POPCs without water quality guidelines.

In the absence of a WQG for EPH, applicable industry standards were reviewed, and the B.C. Petroleum Storage and Distribution Facilities Storm Water Regulation (≤15 mg/L) was adopted as the MDO, as it represents the most conservative and relevant specification available. In addition, discharges to Howe Sound fall under the *Fisheries Act*, including the Wastewater Systems Effluent Regulations, which set a monthly average TSS limit of ≤25 mg/L; this value is therefore adopted as the MDO for TSS. A summary of the MDOs is presented in Table 4-8.

Table 4-8:
Summary of Minimum Discharge Objectives for POCs

Parameter of Concern (POC)	Minimum Discharge Objective (MDO)	Rationale
EPH	≤15 mg/L	Adopted from B.C. *Environmental Management Act* Petroleum Storage and Distribution Facilities Storm Water Regulation, B.C. Reg. 177/2023 as most relevant and conservative discharge specification.
TSS	≤25 mg/L	Applied from *Fisheries Act* Wastewater Systems Effluent Regulations (SOR/2012-139).

4.2.1.4 BAT Selection

The BATA recommends a targeted treatment strategy using an on-site wastewater treatment system to address EPH and TSS concentrations from contaminated or potentially contaminated contact water. Several treatment options are evaluated, including vacuum truck removal with off-site disposal, filtration/adsorption, biological treatment, and oil-water solids separation. After considering feasibility, reliability, operational complexity, control effectiveness, and cost-effectiveness, the BATA selected an oil-water solids separation system (*i.e.*, the OWTS) as the best available technology for treating EPH and TSS.

4.2.2 Design Criteria

Physical removal by oil-water separation is commonly used to treat oil-contaminated water. This option uses physical forces (*i.e.,* gravity and buoyance) to separate suspended solids and oil in the contaminated water. The water enters a vessel which allows the suspended solids to settle (gravity) and the oil droplets to rise (buoyancy). The contaminants (*i.e.,* free oil and solids) are collected for transport to an offsite disposal facility. The operational complexity is low for oil-water separators that rely on physical forces. Because these systems rely primarily on gravity, they require very little power to operate. Coalescing media improves oil removal compared to conventional gravity separators. Media fouling over time requires cleaning or replacement.

Design criteria for the OWTS is summarized in the sub-sections below, including a system overview (Section 4.2.2.1), retention times (Section 4.2.2.2), instrumentation (Section 4.2.2.3), treatment residuals (Section 4.2.2.4), conveyance of OWTS influent (Section 4.2.2.5), and discharge of OWTS effluent (Section 4.2.2.6). Detailed OWTS design criteria are provided in the McDermott document: Unit 64 Effluent and Wastewater System – Process Design Basis (MDR, 2025c; Appendix 4.2-2).

4.2.2.1 Oily Water Treatment System Overview

This section provides an overview of the treatment components and processes used in the design of the OWTS (Appendix 4.2-2). The piping and instrumentation diagrams (P&IDs) for the Oily Water Storage Tank and OWTS are provided in Appendix 4.2-3, along with legends of piping and instrument symbology used on the P&IDs. The OWTS is located on the east side of Mill Creek (Figure 4-4, Section 4.1.5) and is adjacent to the operational process areas that represent the primary sources of EPH and TSS. The OWTS consists of:

- Two 30 m^3/hr inlet feed pumps (01-P-6417-21 A/B) (one operating; one in standby);

- One Corrugated Plate Interceptor (CPI) separator (01-H-6417-41);
- Two treated water forwarding pumps (01-P-6417-22 A/B) (one operating; one in standby); and
- Associated piping, wiring, instrumentation, and controls.

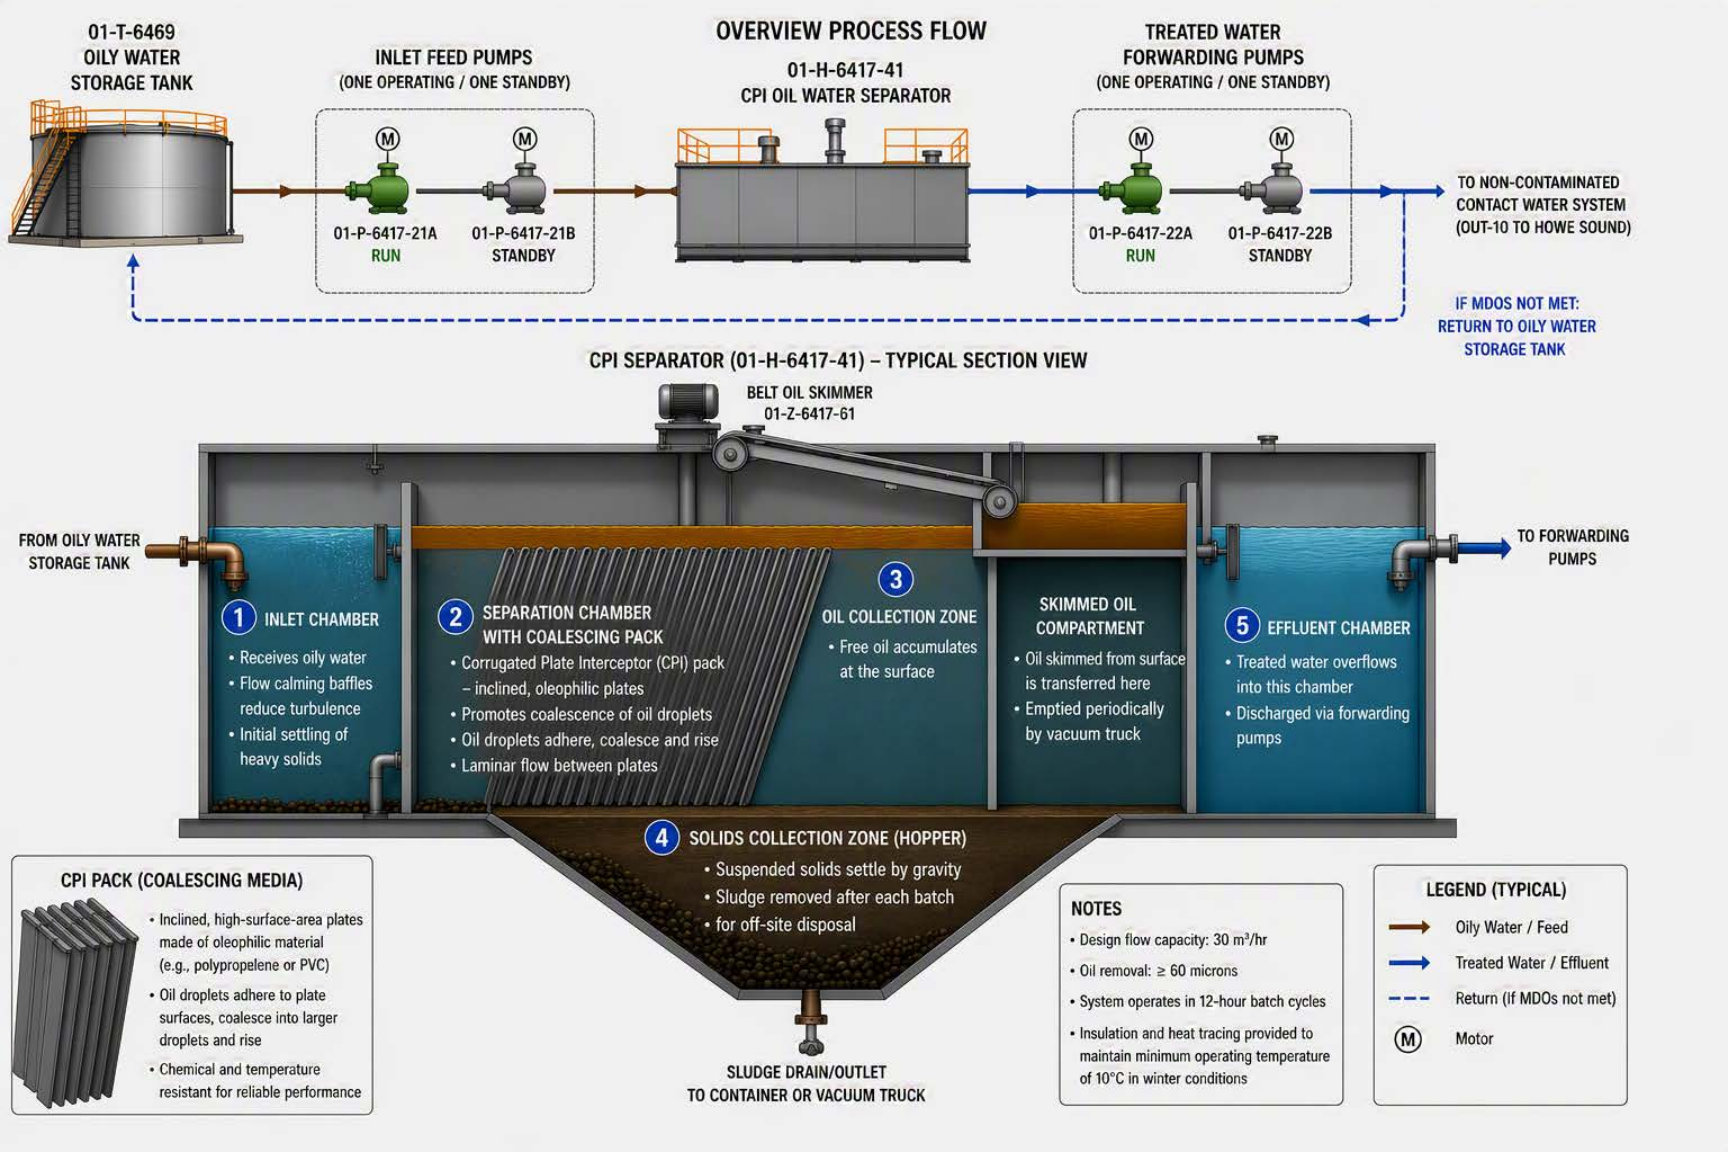
Feed pumps transfer contaminated water stored in the Oily Water Storage Tank to the OWTS. The OWTS operates in 12-hour batch cycles. Insulation and heat tracing are provided to maintain the minimum operating temperature of 10°C during winter and snowfall conditions.

The CPI separator is designed to remove oil droplets ≥60 microns at a maximum flow of 30 m^3/hr. It includes a CPI pack and a motorized belt skimmer. As oily water flows through the CPI pack, oil rises to the surface, while suspended solids settle to the bottom of the hopper. The skimmer operates continuously during OWTS operation, transferring recovered oil to the skimmed oil compartment, which is emptied periodically by vacuum truck (after approximately 10 batch cycles). The suspended solids present in the water are separated by gravity. Sludge collected in the hopper is removed after each batch for off-site disposal. Treated water overflows into the treated water compartment and is discharged via forwarding pumps to the non-contaminated contact water system through the outlet line.

Details of the Oily Water Storage Tank and the OWTS are further described in the sub-sections below. A conceptual schematic is provided in Figure 4-12.

4.2.2.1.1 Oily Water Storage Tank

The purpose of the Oily Water Storage Tank (01-T-6469) is to hold the incoming flow collected from the contaminated and potentially contaminated contact water collection systems (Section 4.1.5.1 and Section 4.1.5.2, respectively), allowing the downstream OWTS to operate in a stable condition. The Oily Water Storage Tank is an above-ground tank that is epoxy-lined with cathodic protection. The Tank is provided with heating coils to maintain temperature and floating oil skimming capabilities to skim any oil from the tank. Skimmed oil is sent offsite to appropriate waste management facilities. Oily water from Oily Water Storage Tank is pumped via the Oily Water Storage Tank Pump (01-P-6417-21A/B) to the downstream OWTS.



4.2.2.1.2 Oily Water Treatment System

The OWTS (01-A-6417) is installed above-ground and is designed to remove free oil (*i.e.*, EPH) and TSS from the water collected in the Oily Water Storage Tank. The system operates as a CPI separator, using gravity separation enhanced by coalescing media to

improve the removal of free oil and suspended solids from the water. Oil droplets, being less dense than water, naturally rise to the surface under gravity. The coalescing pack accelerates this process by promoting droplet collision and merging (coalescence), forming larger droplets that separate more efficiently. Key components include the:

1) Inlet Chamber: Receives oily water from the Oily Water Storage Tank. Flow is controlled to minimize turbulence and allow initial settling of heavy solids.
2) Separation Chamber with Coalescing Pack: A set of inclined, high-surface-area plates is installed within the Separation Chamber to promote laminar flow conditions. As water moves between these plates, small oil droplets collide with the plate surfaces and adhere due to surface tension. Over time, these droplets merge into larger ones through coalescence. Once the buoyant force acting on the enlarged droplets exceeds their adhesion to the plate surface, they detach and rise rapidly to the water's surface. CPI plates are constructed from oleophilic materials such as polypropylene or PVC, which promote strong molecular attraction between the plate surfaces and oil droplets. This allows the droplets to adhere to the plates more effectively than with conventional materials, which primarily trap droplets by obstructing their rise path. In addition, these materials offer excellent resistance to chemical agents and temperature variations, ensuring reliable performance under varying operating conditions.
3) Oil Collection Zone: Free oil accumulates at the top and is skimmed to the Skimmed Oil Compartment.
4) Solids Collection Zone: Suspended solids present in the water settle to the bottom forming sludge, which is periodically removed.
5) Effluent Chamber: Discharges treated water and is equipped with instrumentation for level and quality monitoring (refer to Section 4.2.2.1.3).

The separated oil and accumulated sludge collected within the OWTS will be periodically removed into suitable containers or vacuum trucks for off-site disposal.

Note: image generated by Microsoft Copilot, 2026. For illustrative purposes only. Refer to Appendix 4.2-3 for OWTS design drawings.

Figure 4-12: Conceptual Schematic of the Oily Water Treatment System and Associated Components.

4.2.2.1.3 Treated Effluent Discharge

Treated effluent from the OWTS that meets MDOs will be pumped through a pipeline (Figure 4-4, Section 4.1.5) to the non-contaminated contact water system (Section 4.1.5.3) which discharges to Howe Sound through OUT-10. Effluent from the OWTS that does not meet MDOs will be returned to the Oily Water Storage Tank for additional treatment until MDOs are achieved.

4.2.2.2 Retention Times

Retention times for the Oily Water Storage Tank and the OWTS are summarized in Table 4-9 below. Retention time in the Oily Water Storage Tank will vary with operational conditions, with a minimum requirement of approximately 15 minutes. However, the design allows for significantly longer retention if needed, given the nature of batch operations.

Table 4-9:
Retention Times of Oily Water Treatment Components

Treatment Component	Specification
Oily Water Storage Tank	
Tank size	7.5 m (I.D.) x 12 m (H)
Capacity (net working)	444 m^3
Retention time	> 30 minutes
CPI Separator Tank	
Tank size	6.2 m (L) x 2 m (W) x 3 m (H)
Capacity	37 m^3
Retention time	42 min

Note:
I.D. = inner diameter; H = height; L = length; W = width.

4.2.2.3 Instrumentation

Instrumentation will be used to support the operation of the Oily Water Storage Tank and the OWTS. A summary of the primary instruments is provided below, while more detailed information can be found in the McDermott document: *Control Philosophy and Logic Diagram* (MDR, 2024b; Appendix 4.2-6-3).

The Oily Water Storage Tank is monitored through level indicator in the control room, with alarms provided at high and high-high levels for operator intervention. To protect the inlet feed pumps, a low-level signal from the level indicator will automatically stop the feed pumps.

Within the CPI separator, flow is measured by a flow transmitter to ensure the maximum operating flow rate of 30 m³/hr is maintained. The motorized belt skimmer is monitored using motor run feedback, which triggers an interlock to close the inlet valve if the skimmer stops. Oil collected in the skimmed oil compartment is tracked by a guided wave radar level transmitter, supplemented by a local sight glass. A high-high level signal from the level transmitter will shut down the inlet feed pumps to prevent overflow. Sludge in the hopper cannot be detected by a transmitter due to its low concentration, so visual monitoring is provided via a sight glass.

Treated water flows into a dedicated compartment within the CPI separator, where a level transmitter controls the treated water forwarding pumps. Pump protection is provided by another level transmitter, which initiates a shutdown on low-low level. The discharge line includes two oil-in-water analyzers and two ON/OFF valves: one for the treated water line and one for the off-spec return line. To allow for operational buffer with the MDO (15 mg/L), if the EPH concentration exceeds 10.5 mg/L, the valves will automatically switch to redirect water back to the Oily Water Storage Tank for re-treatment. When the concentration returns to specification, the valves reverse to allow discharge to the non-contaminated contact water system.

For winterization, all pumps, piping, valves, and instruments are equipped with electric heat tracing and insulation to maintain a minimum temperature of 10°C. The CPI separator also includes two electrical heaters controlled by temperature transmitters, with activation and deactivation setpoints at 10°C and 38°C respectively.

Control of the OWTS is managed by a Programmable Logic Controller (PLC) based system located remotely and integrated with the Distributed Control System (DCS). The Unit Control Panel (UCP) supports automatic, manual, and off-line modes and includes a local Human-Machine Interface (HMI) panel for monitoring and operational adjustments. A local power distribution board within the OWTS package supplies all electrical components, including pumps, skimmer motor, heaters, heat tracing, and instrumentation.

4.2.2.4 Treatment Residuals

Residual waste from the Oily Water Storage Tank and the OWTS consists of two primary streams: recovered oil and sludge. Oil recovered from the CPI separator at approximately 70% concentration is stored in the skimmed oil compartment and removed periodically (typically every 10 batch cycles) using a vacuum truck. A safety margin allows for up to five additional cycles if removal is delayed. Each 12-hour batch is expected to produce approximately 0.1 m³ of residual oil. In addition, skimmed oil from the Oily Water Storage Tank is routed from the skimmer to temporary containment via piping prior to offsite disposal.

Sludge, collected in the CPI separator hopper at roughly 1% concentration, is removed after each batch using a vacuum truck and transferring into suitable containers for temporary storage onsite prior to offsite disposal. Each 12-hour batch is anticipated to generate approximately 2.7 m^3 of sludge. Because sludge cannot be detected by a transmitter, visual monitoring is provided via a sight glass, and an operator alarm is triggered every 12 hours. A six-hour safety margin is included to prevent sludge carryover into treated effluent if removal is delayed. Grab samples of the sludge will be analyzed for the parameters required by the waste disposal facility.

All residual waste will be transported to an off-site, provincially licensed facility. Facilities in the B.C. Lower Mainland that can accept treatment system residuals currently include (but not limited to): GFL Environmental (Squamish), Secure Energy (Richmond), Sumas Environmental (Burnaby), and Clean Harbours (Delta). Waste shipment frequency will depend on seasonal conditions, with the highest frequencies expected during periods of heavy rainfall. Wastes will be managed in accordance with the Operations Waste Management Plan, that will be developed in accordance with the EAC.

Further details on treatment residuals for the Project are outlined in Section 3.3 of the SWDMP (Appendix 4.1-1).

4.2.2.5 Conveyance of OWTS Influent

Contaminated and potentially contaminated contact water systems (Section 4.1.5.1 and Section 4.1.5.2, respectively) convey oily water to the Oily Water Storage Tank. The contents of the tank are pumped to the OWTS as described in Section 4.2.2.1. A sample port is installed between the Oily Water Storage Tank and the OWTS to allow for influent quality testing.

4.2.2.6 Discharge of OWTS Effluent

Treated effluent from the OWTS that meets all MDOs is discharged to the non-contaminated contact water system which discharges to Howe Sound at OUT-10, as described in Section 4.2.2.1. The treated water line for the OWTS is equipped with two oil-in-water (*i.e.,* EPH) analyzers for real-time monitoring that will be used to confirm that treated effluent meets the control specification (≤10.5 mg/L) used to provide operational buffer on the EPH MDO (15 mg/L), and to operate the effluent control valves described in Section 4.2.2.3. If oil concentration exceeds 10.5 mg/L EPH, the valves automatically switch to redirect water back to the storage tank for re-treatment. When the concentration returns to specification (≤10 mg/L EPH), the appropriate valve will open to allow discharge to the non-contaminated contact water system. The effluent line of the OWTS is equipped with a sample port connection for period sampling of effluent quality.

The TSS concentration in treated effluent is managed using field turbidity measurements. A turbidity-TSS relationship will be established as described in Section 6.2.5, and will be used to confirm that TSS meets the treatment specification (≤25 mg/L). A threshold turbidity value with a safety buffer set below the equivalent of 25 mg/L TSS will be established. This approach will enable personnel to estimate TSS in real time from turbidity readings and make conservative discharge decisions, given the time required to obtain TSS analysis results from a laboratory.

4.2.3 Treatment Effectiveness

The CPI separators are a proven and widely used technology for removing oil (*i.e.*, EPH) and TSS from industrial wastewater. Operating on gravity separation principles, CPI units use corrugated plates to enhance oil droplet coalescence and improve separation efficiency. This technology is recognized as reliable and robust, with decades of successful application in oil and gas, mining, and petrochemical industries. Its design and performance are well understood, ensuring predictable treatment outcomes when properly sized and maintained. The simplicity of the separation mechanism, combined with decades of proven application, provides a high level of confidence in treatment performance without the need for bench-scale validation. However, to provide additional assurance, the OWTS vendor, Cannon Artes, has issued a Process Guarantee (Appendix 4.2-4) confirming the system's capability of achieving MDOs. Cannon Artes has extensive experience designing and installing CPI systems worldwide. A list of Cannon Artes's project experience with CPI separators that are technically similar to WLNG's proposed treatment process and treated water discharge criteria is included in Appendix 4.2-5.

4.2.4 Primary Performance Risks and Mitigation

The overall objective of the OWTS is to sufficiently treat contaminated and potentially contaminated contact water generated within the facility and to produce discharge water that meets the MDOs. A variety of challenges that have the potential to impact the operation and effectiveness of the OWTS (if unmitigated) have been identified, including power outage, reagent supply interruption, and variable flow conditions. A summary of primary challenges for the OWTS and a high-level management approach for each is presented in the SWDMP (Appendix 4.1-1), along with relevant management plans (summarized in Sections 4.1.6, 4.1.7, 4.1.8, and 4.1.9).

4.2.5 Operation and Manual

The OWTS vendor, Cannon Artes, has provided a comprehensive Operating and Maintenance Manual (MDR, 2025a; Appendix 4.2-6-1). Supplemental information is

included in the following documents: Schedule of Manufacturer's Commissioning and Start-Up and 2 Years Operation Spares (MDR, 2025b; Appendix 4.2-6-2), Control Philosophy and Logic Diagram (MDR, 2024b; Appendix 4.2-6-3), and Cause and Effect Charts (MDR, 2024a; Appendix 4.2-6-4). The manual and supplementary documents include preventative maintenance programs, operator training requirements, inspection schedules, spare parts inventory, and alarm response protocols. Key information regarding OWTS maintenance, monitoring, and operator training is summarized below.

4.2.5.1 Maintenance

The OWTS operates in batch mode, allowing routine and corrective maintenance to be scheduled without impacting treatment performance. Preventative maintenance will include routine lubrication and inspection of all driven equipment, along with scheduled checks of safety valves and pressure, level, and flow control devices. A structured maintenance program will define routine tasks and trigger levels for unscheduled work. Regular inspections of all units, including verification of pressure, level and flow regulating equipment, are essential for reliable operation. A complete running log will be maintained to ensure accurate control and smooth plant performance.

4.2.5.2 Monitoring

A daily monitoring log will record key operating parameters such as pressure, flow rate, and turbidity. Normal operating conditions will be established and used as benchmarks to identify deviations that may indicate maintenance needs or troubleshooting requirements. Influent and effluent monitoring requirements are detailed in Section 6.2.1. Visual inspections of major components (*i.e.*, tanks, pumps) and the piping network (*i.e.*, valves, sampling ports) will also be conducted daily, with findings documented in the log.

4.2.5.3 Operator Training

The OWTS vendor, Cannon Artes, is responsible for training WLNG technical personnel at the Project site. This training ensures operators acquire the skills necessary to operate the system safely and efficiently, including responding to real-world and emergency situations without compromising personnel or OWTS safety.

Training is delivered by a qualified site supervisor and includes both theoretical instruction and practical exercises, such as simulated operations in the Unit Control Panel (UCP). Each session concludes with a question-and-answer segment. The training program covers the following topics: safety procedures, common terminology, chemical and physical process theory, unit description and system overview, design criteria, equipment operation, control philosophy and start-up procedures, troubleshooting and problem-solving, and

maintenance requirements. Upon completion, each participant receives a personal attendance certificate.

4.2.6 Performance Testing

As part of planned commissioning activities, the OWTS will undergo both functional and performance testing. All OWTS components, including instrumentation, analyzers, and operating and alarm set points, will be functionally tested using uncontaminated water. The system will be operated in recirculation mode for multiple cycles to verify successful overall functional performance.

Once the system has been confirmed to be functionally operating as designed, the system will be shut down to conduct a performance test. Performance testing of the OWTS shall be completed during commissioning prior to the system being placed into operational service and prior to authorization of routine discharge through OUT-10. Performance testing shall include:

- verification of hydraulic performance;
- calibration and verification of oil-in-water analyzers;
- verification of automatic diversion logic for off-specification effluent;
- verification of containment and recovery systems;
- confirmation of sludge and oil removal functionality;
- process upset simulations; and
- treated effluent quality testing.

Performance testing shall include a controlled challenge test utilizing a biodegradable test oil or equivalent environmentally acceptable hydrocarbon surrogate introduced into the system under controlled conditions to demonstrate the oil separation and diversion capabilities of the system. The challenge testing shall:

be conducted in a closed-loop or recirculation configuration where practicable;

- prevent uncontrolled discharge to Howe Sound during testing (outlet line to the non-contaminated contact water system will be blocked);
- include collection of influent and effluent analytical samples;
- verify operation of oil skimming and sludge handling systems;
- verify analyzer response and diversion valve operation during elevated oil concentration conditions; and
- demonstrate return to compliant operation following upset recovery.

Effluent generated during performance testing that does not meet discharge requirements shall be diverted back to the Oily Water Storage Tank, recycled within the system, or removed from site for appropriate disposal.

Once it has been confirmed that treated effluent consistently meets the discharge limits specified by the WDA, the system will be shut down, and the test water and recovered oil will be drained and disposed of in an appropriate manner. Upon successful completion and acceptance of the test, the OWTS will be refilled with uncontaminated water and restarted in recirculation mode. After verification of normal operation, the OWTS may be placed into service.

Final acceptance of the OWTS shall require successful completion of performance testing, operational readiness review, and confirmation that the system can achieve the applicable discharge objectives and permit requirements under anticipated operating conditions.

4.2.7 OWTS Commissioning Schedule

The proposed schedule for the commissioning of the OWTS is presented in Table 4-10 below (note, this is subject to change pending system readiness). Commissioning of the oily water collection system (including sumps, pumps, and piping) will occur prior to commissioning the OWTS, as described in Section 4.1.10.

Table 4-10:
Proposed OWTS Commissioning Schedule

Activity	Planned Start	Approximate Duration (days)
Commissioning of Oily Water Collection System	Q2 2027	11
Commissioning of Oily Water Treatment System	Q2 2027	4

The commissioning schedule for the OWTS is integrated with the overall LNG facility commissioning and start-up schedule. The intent is for the permanent drainage collection systems, sump systems, monitoring instrumentation, diversion systems, and OWTS to be commissioned and operational prior to introduction of hydrocarbons or other environmentally significant process fluids into the associated LNG process areas.

Hydrocarbon introduction into process systems connected to contaminated contact water drainage systems shall not proceed unless:

- the associated drainage collection systems are operational;
- diversion and containment systems are available;
- oil-in-water analyzers are calibrated and functional;
- off-specification routing has been verified; and

- the OWTS has successfully completed functional and performance testing.

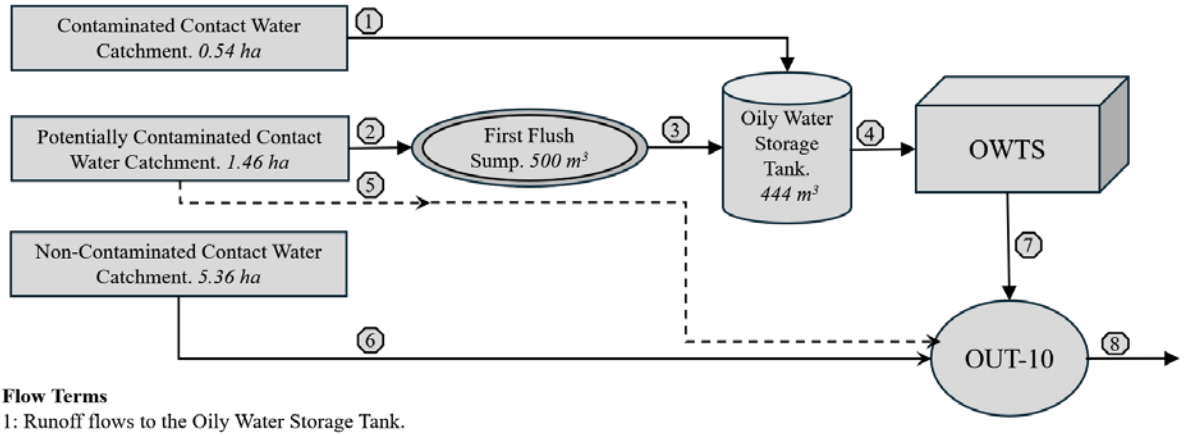
Temporary measures, including vacuum truck support, temporary containment, temporary storage tanks, or temporary diversion arrangements, may be utilized during transitional commissioning phases where required to maintain environmental protection and regulatory compliance.

4.3 Effluent Model

A water balance and water quality model (the "effluent model") is developed for the Project to simulate the expected quantity and quality of contact water that will be generated. The effluent model is designed to predict flow and water quality for the OUT-10 node and to model water quality for untreated contact water (OWTS influent), OWTS treated effluent, non-contaminated contact water and non-contact water. Source terms are developed to predict the quality of these waters (refer to Section 4.3.2). Discharges via OUT-10 include:

- Treated effluent from the OWTS (which discharges into the non-contaminated contact water management system); and
- Stormwater from the potentially contaminated and non-contaminated contact water systems during storm events.

The effluent model accounts for planned water management activities and applies a mass balance approach to calculate OUT-10 discharge water quantity and quality during a 2 year 24-hour storm event. The model predictions are used to assess whether the expected effluent concentrations of any POCs and POPCs will potentially exceed applicable water quality guidelines and therefore may need to be included in a WDA pursuant to the B.C. *Environmental Management Act*.



The other outfalls shown in Figure 2-1 will discharge non-contact water, non-contaminated contact water, and creek water as described in Section 4.1.3. The water quality discharged from OUT-01, OUT-02, OUT-04, OUT-06, OUT-11, OUT-12 or OUT-13 is expected to be similar to non-contact water quality presented in Section 3.6.3 (Table 3-23). East Creek discharges through OUT-12; during operations, water quality in East Creek is expected to remain within the historical ranges outlined in Section 3.6.3 (Table 3-19).

The effluent model predictions include results for two scenarios: expected case and extreme case. The two scenarios are differentiated by water quality source terms used in each scenario, whereby the median and 90th percentile statistics calculated from water quality monitoring data are applied to the expected and extreme case, respectively. The derivation of the expected and extreme case water quality source terms is described in Section 4.3.2.

The OUT-10 effluent model structure and processes are described in the following sections, with details specific to the water balance and water quality source terms included in Section 4.3.1 and Section 4.3.2, respectively. The effluent model predictions are presented in Section 4.3.3.

4.3.1 Effluent Model Water Balance

The effluent model water balance was developed from the site hydraulic model (Stantec, 2026a) for a 24 hour 2-year return period rain-on-snow storm event precipitation depth (157mm) to calculate the resultant discharge volumes at OUT-10. The water balance is a simplified version of the water management system described in Section 4.1.5. The simplified approach assumes all contaminated contact water is directed to the Oily Water Storage Tank, and does not account for storage that is available in contaminated contact water sumps located upstream of the tank, or for the portion of the contaminated contact water catchment that is redirected to the First Flush Sump Diversion Box after the first flush rainfall amount (*i.e.*, the first 25 mm of rainfall). The water balance assumes all treated water is suitable for discharge. Variations in hourly rainfall intensity that are typical of storms are accounted for using the Soil Conservation Service (SCS) Type 1A distribution with 24-hour duration, consistent with the approach used in Stantec (2026a). The conceptual water balance and hourly rainfall intensities are shown in Figure 4-13 and Figure 4-14, respectively.

Flow Terms
1: Runoff flows to the Oily Water Storage Tank.
2: Runoff flows to the First Flush Sump during first flush only (first 25mm precipitation). Flows stops at end of first flush period.
3: After flow stops, water stored in First Flush Sump is conveyed to Oily Water Storage Tank.
4: Actively managed flow to OWTS at 30 m^3/hr. Flow modelled to start one (1) hour after start of runoff.
5: Runoff flows after first flush report to OUT-10 via the non-contaminated contact water system.
6: Runoff from non-contaminated contact areas reports directly to OUT-10 via the non-contaminated contact water system.
7: OWTS treated effluent discharged to OUT-10 via the non-contaminated contact water system.
8: Discharge to Howe Sound from the non-contaminated contact water system.

Figure 4-13: Conceptual Effluent Model Water Balance (Simplified Version of the OUT-10 Water Management System Described in Section 4.1.5)

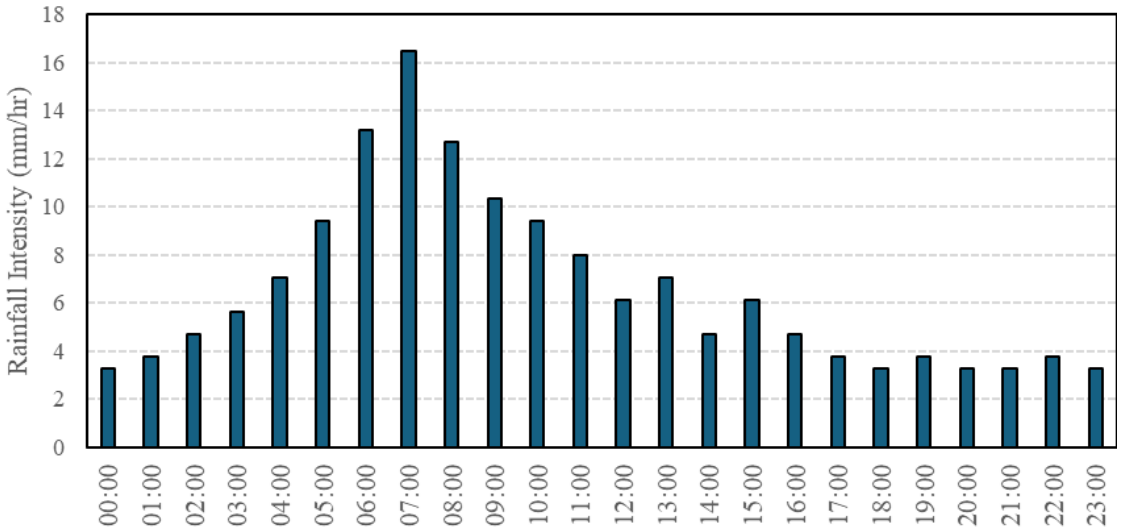


Figure 4-14: Hourly Precipitation Intensity for a 24 Hour 2-Year Return Period Storm Event with SCS Type 1A Distribution

The water balance incorporates storm event precipitation and runoff coefficients that were assigned to each discrete physical area delineated in the model. Precipitation is transformed into one-minute time step flows using the respective runoff coefficient for each catchment using the following equation:

$$Q = 1.66 \bullet A \bullet C \bullet I$$

where Q is the runoff rate (m^3/min), A = catchment area (ha), C = runoff coefficient (dimensionless) assigned to area A, and I = precipitation intensity (mm/hr). It is necessary to run the model at a one-minute time step to adequately quantify the filling and outflow from the First Flush Sump and the Oily Water Storage Tank. The overall catchment area for OUT-10 is shown in Figure 4-3 (Section 4.1.3) and the water management systems included in the water balance are described in Section 4.1.5. The contaminated contact area is estimated by summing the contaminated water system sump footprints and adjacent containment areas shown in Figure 4-4 (Section 4.1.5). The size and runoff coefficient assigned to each catchment area are presented in Table 4-11.

Table 4-11:
Catchment Areas and Runoff Coefficients Included in Effluent Model

Catchment	Land Type	Area (ha)	Runoff Coefficient[1]
Potentially Contaminated Contact Area	Impervious Area	1.46	1.00
Contaminated Contact Area	Impervious Area	0.54	1.00
Non-Contaminated Contact Area	Mostly Gravel Area	5.36	0.85

Notes: [1] Runoff coefficients sourced from Stantec (2026a).

Water quality parameters tracked by the model are treated as conservative tracers which are mixed at the OUT-10 model node (confluence) by the following equation:

$$C_r = \frac{\sum_i Q_i C_i}{\sum_i Q_i}$$

where C_r is the resultant concentration, $Q_i$are the source flows into the mixing point and $C_i$are the concentrations associated with the source flows.

A key objective of the effluent model is to incorporate the water management decision matrix for managing stormwater runoff from potentially contaminated areas as described in Section 4.1.5.2. The potentially contaminated water system directs potentially contaminated water to the Diversion Box, which directs water to the First Flush Sump or to the non-contaminated contact water system in larger storm events. As discussed in Section 4.1.5.2, initial runoff (*i.e.,* the first flush) from potentially contaminated areas is collected in the First Flush Sump and is monitored for POCs prior to discharge or treatment, based on monitoring results. It is expected that after the first 25 mm of rainfall, only non-contaminated water will be collected at the First Flush Sump, and the Diversion Box will overflow to the non-contaminated contact water system for discharge via OUT-10. Therefore, the water balance for OUT-10 assumes that initial flows to the Diversion Box are directed to the First Flush Sump, and after 25 mm of rainfall, the Diversion Box flows are redirected to OUT-10. The accumulation of the initial 25 mm of precipitation is modelled to occur, approximately, during the first five (5) hours of rainfall. The effluent model illustrates the condition where all sumps in the contaminated water system are directed to the Oily Water Storage Tank, and the following assumptions are made:

- Sumps upstream of the Diversion Box do not contain POCs that require off-site disposal or storage for dispersion by evaporation, and therefore do not store water.
- The First Flush Sump is assumed to be empty at the start of the model, and the first flush water volume is directed to the OWTS for treatment.
- The Oily Water Storage Tank is assumed to be empty at the start of the model. Water from the Tank is conveyed to the OWTS at a rate of 30 m^3/hour (8.3 L/s). To allow for the accumulation of water in the tank prior to treatment, transfer to the OWTS is initiated at 01:00 hour.
- The OWTS is assumed to have no storage capacity, and outflow rate is set to the inflow rate of 30 m^3/hour (8.3 L/s).
- The contaminated water catchment area (0.54 ha) is assumed to be equal to the sum of areas for the sump footprints and the bermed areas for Module 01, Module 02, and the Condensate Storage Area (Figure 4-4).

- The potentially contaminated catchment area (1.46 ha) is calculated as the difference between the 2.0 ha total area estimated in the BATA (MDR, 2026b; Appendix 4.2-1) for the contaminated and potentially contaminated contact water catchments, and the contaminated contact water catchment (0.54 ha) described above.
- The non-contaminated catchment area (5.6 ha) is equal the difference between the OUT-10 total catchment area (7.6 ha) and the contaminated and potentially contaminated contact water catchment areas (2.0 ha) the gravel covered areas.

4.3.2 Water Quality Source Terms

The water quality component of the effluent model follows the water balance schematic for the OUT-10 catchment (Figure 4-13). The concentration of 113 parameters are modelled, which include TSS, pH, nutrients, anions, total and dissolved metals, non-halogenated VOCs, PAHs and EPH. Parameters with WQGs for the protection of FWAL and MWAL, or flagged as POCs, were included in the model, as well as additional parameters that are generally useful for evaluating water quality. Water quality source terms are developed for untreated contact water (OWTS influent), OWTS treated effluent, non-contaminated contact water and non-contact water. The source terms are derived from Project water quality monitoring data, and from information provided in the BATA (MDR, 2026b; Appendix 4.2-1).

Two source term scenarios are modelled, the expected case and extreme case, to address the uncertainty associated with source term derivation. The expected case model source terms are set to the median values and are considered to represent the mid-point parameter concentrations under normal conditions. The extreme case model results are derived using the 90th percentile concentrations and represent an upper range of potential concentrations, which are considered significantly less likely to occur than expected case, and to occur infrequently.

For alkalinity, dissolved oxygen, pH and TDS, the 10th percentile value was used to model the extreme case. The 10th percentile was selected for pH and dissolved oxygen because these parameters have WQGs that are bounded by minimum values, and as discussed in Section 3.6.3.1, low pH is a natural condition of freshwater at the Project site. Therefore, the 10th percentile is more appropriate for modelling the extreme condition for dissolved oxygen and pH. Low pH values at the Project site are associated with low alkalinity and low TDS concentrations; therefore, the 10th percentile of these parameters is also selected for the extreme scenario.

4.3.2.1 Derivation Overview

The water quality source terms are derived from multiple sources. Water quality data from the Project non-contact diversion ditches are used to establish the background characteristics of stormwater runoff (refer to Section 4.3.2.2). The concentration of TSS in non-contact water is generally low and not suitable for modelling loadings of parameters that are typically associated with TSS. Therefore, non-contaminated construction contact water quality is used to calculate loading rates for particulate-bound forms of parameters associated with TSS, and the loadings are added to the background concentrations derived from non-contact water. The OWTS design specifications for EPH and TSS outlined in Appendix 4.2-1 are used as the source terms for EPH and TSS in the OWTS influent and effluent. Process reagents and petroleum hydrocarbons that are identified in Section 4.1.2 to be mitigated by source controls such as secondary containment followed by off-site disposal or weathering, are excluded from the effluent model.

4.3.2.2 Background Water Quality

Background water quality is derived from the non-contact water diversion ditch dataset described in Section 3.6.3. The diversion ditches intercept hillside runoff flowing towards the Project site, and during the dataset monitoring period (April 2022 to May 2025), significant sections of the ditches were unlined and constructed in alluvial gravel that have been flushed free of fine sediments. Considering that there are no activities (*i.e.,* civil works) during operations that are expected to produce TSS within the Project site, and that stormwater will flow on impermeable surfaces (*i.e.,* concrete or asphalt) or compacted gravel surfaces, the non-contact diversion ditch water quality is considered a proxy for background stormwater quality during operations.

The non-contact dataset consists of 77 samples that span the April 2022 to May 2025 period. In general, the diversion ditch water is clear with low concentrations of TSS and is not suitable for deriving loadings of parameters that are typically associated with TSS, such as total metals and organic compounds. Therefore, the median and 90th percentile statistics are used to represent expected case and extreme case background water quality for TSS, general parameters, nutrients, anions and dissolved metals.

For statistical calculations, non-detectable results are generally set equal to the reporting limit values. However, for some dissolved metal parameters (*i.e.,* Pb, Li, Hg, Ni, Se, Ti and V), a range of values are reported for non-detectable results, and the highest reporting limits are well above the highest detectable concentration. For other dissolved metals (*i.e.,* Ag, Be, Bi, Cr[VI], P, Sn and Tl), virtually all the results for a parameter are reported as non-detectable. Therefore, the following data filtering approach is used for non-detectable dissolved metal values:

- Statistical calculations are conducted on the subset of the dissolved metals data that only includes detectable results. For each parameter, the statistics from the subset are compared to the reporting limit value for each non-detectable result from the uncensored data.
- If greater than 5% of results are detectable, and the 95th percentile of the detectable result subset is greater than the highest reporting limit value, all non-detectable results are assigned the reporting limit value.
- If greater than 5% of results are detectable, and the 95th percentile of the detectable result subset is less than a reporting limit value, and the maximum of the detectable result subset is less than 2 times that same reporting limit, then all non-detectable results with that reporting limit value are excluded from source term dataset. Otherwise, non-detectable results are assigned the reporting limit value.
- If less than 5% of results are detectable all non-detectable results are assigned a zero value.

The screened dataset is used for statistical calculations, and the resulting statistics are tabulated in Appendix 4.3-1.

4.3.2.3 Parameters Associated with TSS

The modelled concentrations of parameters associated with TSS are derived using non-contaminated construction contact water monitoring results collected October 2025 to January 2026 from the Project site (Appendix 4.3-2). During this period the site was covered with fill or impermeable surfacing (*i.e.,* concrete) that had been placed from 2024 through 2025, and is similar to the materials for the final surfacing that will be in place during operations. The water quality samples were collected from influent to the West Sedimentation Pond (station SP-W-IN) and influent to the 2700 GPM TSS settling system (station 2700GPM-IN). Due to ongoing civil works, the TSS concentrations in construction contact water were elevated up to 497 mg/L. These elevated concentrations of TSS are not considered representative of the water quality expected during operations. However, the elevated concentrations of TSS allow for a derivation of loading rates that can be attributed to particle-bound forms of parameters that are strongly influenced by TSS. Considering that the TSS originates from the Project site, the composition of TSS in the non-contaminated construction contact water data set is a suitable proxy for the composition of TSS during operations.

For each sample in the dataset with a TSS concentration greater than 10 mg/L (*i.e.,* 29 out of a total of 34 samples), the concentration of total metals attributable to TSS is derived by subtracting the dissolved metal concentration from the corresponding total metal

concentration if the total metal is reported as detected; otherwise, that data point is omitted from further calculations. The reporting limits for non-detectable dissolved metals are low and consistent within the dataset; therefore, non-detectable dissolved metal results are assigned the reporting limit value for TSS loading rate calculations. Organic compounds (non-halogenated VOCs, PAHs and EPH) are assumed to be predominantly associated with TSS because they are generally hydrophobic and are likely to adhere to sediment particles. Therefore, the measured concentration is used for loading rate calculations and non-detectable results are set to zero. For each sample, the portion of the total metal or organic parameter concentration attributable to TSS is divided by the TSS concentration to calculate a parameter specific TSS loading rate. The parameter specific loading rates for each sample and the summary statistics are presented in Appendix 4.3-3.

The median and 90th percentile statistics for the TSS loading rates (expected and extreme case, respectively) are used to derive parameter specific loadings from TSS. The concentrations of parameters associated with TSS are calculated by multiplying the modelled TSS concentration with the parameter specific TSS loading rate. This calculation is conducted for the two source term scenarios (expected case and extreme case) modelled for each water type. The results of this calculation are combined with the background water quality to yield the source terms for non-contact and non-contaminated contact water. The source term concentration of each total metal is calculated by summing the TSS component concentration with the corresponding background dissolved metal concentration derived in Section 4.3.2.2. For organic parameters the source term concentration is set equal to the concentration calculated from the TSS loading rate.

4.3.2.4 EPH and TSS

The expected case and extreme case EPH and TSS source terms for non-contaminated contact water and non-contact water are derived from background water quality as described in Section 4.3.2.2 (TSS) and Section 4.3.2.3 (EPH).

The OWTS influent and effluent source terms for EPH and TSS are set equal to the OWTS specifications and objectives outlined in the BATA (MDR, 2026b; Appendix 4.2-1). The OWTS design specification indicates upper limits for influent concentrations of 200 mg/L EPH and 200 mg/L TSS. The discharge objectives for effluent are specified as 15 mg/L for EPH and 25 mg/L for TSS. These values are used as the source terms for OWTS influent and effluent. The same value is applied to both source term scenarios.

4.3.2.5 Source Terms

The median and 90th percentile statistics from background water quality (Section 4.3.2.2) parameter loadings from TSS (Section 4.3.2.3) are combined to form the expected and

extreme case water quality source terms for non-contaminated contact water and non-contact water (Appendix 4.3-4). There are no activities (*i.e.,* civil works) during operations that are expected to produce TSS within non-contaminated areas of the Project site, and stormwater will flow on impermeable surfacing or compacted gravel in these areas. The non-contact catchments are predominantly within vegetated areas, and non-contact water is typically clear flowing during storm events. Although the catchment characteristics differ, the same clear flowing water quality is expected from the non-contact and non-contaminated catchments. Therefore, the same source terms are applied to non-contaminated contact water and non-contact water.

The OWTS influent and effluent source terms are prepared by combining background water quality (Section 4.3.2.2) with the TSS and EPH concentrations (Section 4.3.2.4) and applying the TSS loadings (Section 4.3.2.3) based on the modelled TSS concentration. The median and 90th percentile statistics from the background and TSS loading datasets are used to model the expected and extreme case source term scenarios for most parameters. The 10th percentile values for dissolved oxygen, pH, alkalinity and TDS concentrations are used to represent the extreme scenario for these parameters. The TSS and EPH source terms are conservatively set at the same value for the expected and extreme cases. The source terms for OWTS influent and effluent are tabulated in Appendix 4.3-4.

4.3.3 Effluent Model Results

The modelled flows and water quality at OUT-10 are summarized in this section, as well as the quality of non-contaminated contact water and non-contact water. Discharges from OUT-01, OUT-02, OUT-04, OUT-06, OUT-11 and OUT-13 are stormwater runoff only which is represented by the non-contaminated contact water and non-contact water source term, therefore flows for these outfalls are not included in the effluent model. Untreated contaminated contact water (*i.e.,* OWTS influent) is evaluated against threshold values to conduct a supplementary assessment for POPCs. Predicted water quality discharged at outfalls is screened against federal and provincial WQGs for the protection of MWAL, as well as the no observable effects concentration (NOEC) for EPH that is defined in Section 5.4.5.2. The screening results are presented in summary tables at the end of each sub-section.

4.3.3.1 OUT-10 Flows

The modelled flows for the OUT-10 catchment are presented for each water source that will discharge to Howe Sound through this outfall. Treated contact water from the OWTS is only discharged via OUT-10. The OWTS is expected to be operated primarily during storm events when elevated stormwater flows of contaminated contact water are expected.

However, the OWTS will also be occasionally operated during dry conditions. For example, it may be necessary to empty the Oily Water Storage Tank following, or prior to a storm event, to ensure there is sufficient storage capacity within the tank.

The influence of water management in the OUT-10 catchment is accounted for in the effluent model (Section 4.3.1). Specifically, flows to OUT-10 are modelled for the OWTS effluent, the Diversion Box and the Non-Contaminated Contact Water sub-catchments. To account for the variation in water quality between dry and storm condition discharges at OUT-10, two flow conditions are considered for OUT-10, specifically, a dry condition when the OWTS is the only discharge source, and a storm event when stormwater runoff from non-contaminated and potentially contaminated areas are the dominant source of effluent at OUT-10. During dry conditions, operation of the OWTS the treated effluent is the only source of discharge at OUT-10, therefore a water balance is not established for the dry condition model scenario.

As discussed in Section 4.3.1, the effluent model water balance uses the return statistics for a 1:2-year, 24-hour rain-on-snow storm event (157 mm) to calculate flows to OUT-10 for the storm event scenario. Rainfall intensity over the 24 hour period is modelled using the SCS Type 1A distribution (Figure 4-14).

The modelled water balance for OUT-10 is conducted at an hourly time-step as shown in Figure 4-15. The Oily Water Storage Tank is assumed to be empty at the start of the storm, therefore OWTS is assumed to begin operating one hour after rainfall begins to allow sufficient water to accumulate for treatment. The OWTS treated effluent is modelled to discharge treated effluent to OUT-10 at the 30 m^3/h (8.3 L/s) maximum treatment rate. Potentially contaminated contact water intercepted at the Diversion Box is assumed to be contaminated and is directed to the First Flush Sump until the first flush rainfall amount (25 mm) is modelled to be reached, approximately five hours after rainfall begins. The model assumes that all the first flush water stored in the First Flush Sump is directed to the Oily Water Storage Tank at 30 m^3/h (8.3 L/s) rather than being held back for later treatment. After first flush is completed the flows to the Diversion Box are modelled to be non-contaminated and are added to the non-contaminated contact water discharge flows at OUT-10, with discharge rates of 22.5 to 112 L/s. Stormwater flows from non-contaminated areas range from 33.9 to 169 L/s and are always directed to OUT-10. The total rate of discharge from OUT-10 ranges from 33.9 to 290 L/s during the modelled storm event. The volume of OWTS treated effluent ranges from 2.9 to 17.7% of the total discharge flows, on an hourly basis.

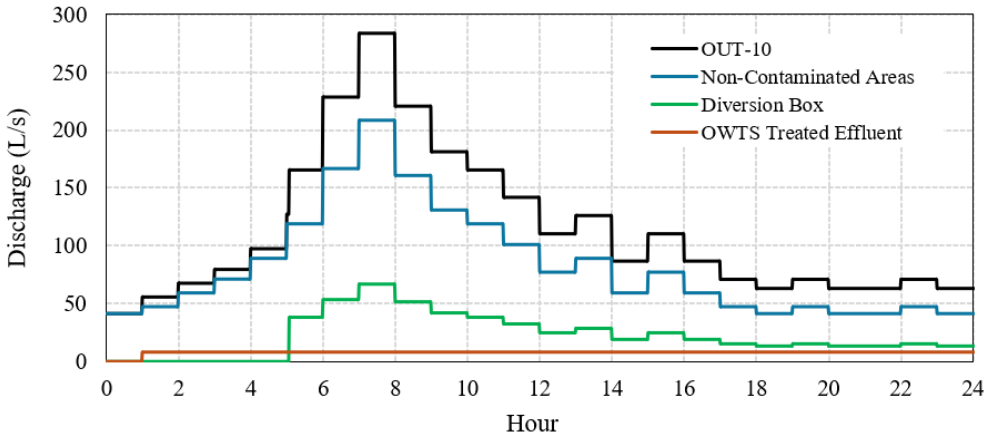

Figure 4-15: Hourly Breakdown of the OUT-10 Water Balance for the Modelled Storm Event.

4.3.3.2 OWTS Influent

The OWTS influent is contaminated or potentially contaminated contact water that is directed to the Oily Water Storage Tank for storage and subsequent treatment. The predicted OWTS influent quality is screened for POPCs to supplement the POPC assessment in the BATA (MDR, 2026b; Appendix 4.2-1). A POPC is defined as any parameter predicted to be greater than 80% of a relevant threshold in untreated effluent (ENV, 2024).

The TSS and EPH parameters identified as POCs in the BATA (MDR, 2026b; Appendix 4.2-1) and are therefore selected for screening. Parameters with a federal or provincial WQG for the protection of MWAL are also selected for screening. For all parameters with WQGs, the guideline values are selected as threshold values. The EPH threshold (2.12 mg/L) is set equal to the no observable effects concentration (NOEC) defined in Section 5.4.5.2 to assess environmental effects associated with EPH.

The OWTS influent expected case and extreme case source terms are screened against 80% of the lowest applicable federal and provincial WQG for the protection of MWAL, and 80% of the NOEC for EPH.

The screening results are presented in Table 4-12. For the expected case and extreme case source terms, the screening results identify EPH, pH, TSS, total cadmium (T-Cd), total copper (T-Cu), total lead (T-Pb), total manganese (T-Mn), total mercury (T-Hg), total vanadium (T-V), total zinc (T-Zn), and benzo(a)pyrene as POPCs. The metal and benzo(a)pyrene parameters are modelled to be associated with TSS and exceed the screening threshold due to elevated TSS concentration (200 mg/L) assigned to untreated contaminated contact water (Section 4.3.2.4). The POPCs carried forward for a POC assessment in Section 5.2. Results for all modelled parameters are tabulated in Appendix 4.3-4.

Table 4-12:
Summary of Predicted OWTS Influent Quality Screened for Parameters of Potential Concern (POPCs)

Parameters	Units	B.C. WQG		CWQG		Untreated Effluent (OWTS Influent First Flush)	
		Long-Term	Short-Term	Long-Term	Short-Term	Expected Case	Extreme Case
General Parameters							
Ammonia, Total (as N) [1,2]	mg/L	2	13	-	-	0.0062	0.050
Fluoride	mg/L	-	1.5	-	-	0.020	0.10
Nitrate as N	mg/L	3.7	-	45	339	0.077	0.22

B.C. WQG = British Columbia working and approved water quality guidelines for the protection of marine aquatic life.
CWQG = Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) water quality guidelines for the protection of marine aquatic life. If a WQG for a parameter is provided by each agency, the lowest value is shown in the table.
Red values are greater than 80% of one or more of the B.C., CCME or ECCC WQGs, or the NOEC (2.12 mg/L) for EPH defined in Section 5.4.5.2.
are identified as a POC in the BATA (MDR, 2026b; Appendix 4.2-1). EPH and TSS are identified at POCs in the BATA.
[1] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. [2] The total ammonia nitrogen B.C. WQG was calculated based on median values for salinity (8.41 ppt), pH (8.05) and temperature (9.46 °C) for CPA stations collected at 0.5 m below surface.
[3] The WQGs for TSS are evaluated assuming the background TSS concentration = 3.0 mg/L (median value of CPA stations 0.5 m below surface).
[4] The B.C. WQG and CWQG for trivalent chromium [Cr(III)] is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the methylmercury concentration and is derived assuming methylmercury is 0.64% of the total mercury concentration (median value from the non-contact diversion ditch dataset).

4.3.3.3 Storm Event Discharges

During storm events, treated OWTS effluent and non-contaminated contact water are both modelled to be discharged at OUT-10, therefore the modelled effluent is a blend of both water types. Non-contaminated contact water will be discharged through OUT-04, through the non-contact water outfalls OUT-01, OUT-02, OUT-06, OUT-11 and OUT-13, as well as the East Creek OUT-12 outfall (Figure 4-3, Section 4.1.3). The parameter concentrations predicted in discharge from OUT-10 are summarized in Table 4-13 and the predicted non-contaminated and non-contact water quality is shown Table 4-14. The results for all modelled parameters are tabulated in Appendix 4.3-4 (non-contaminated water and non-contact water) and Appendix 4.3-5 (OUT-10).

Results are presented for the expected case and extreme case source terms to illustrate the variation in soluble and particulate-bound parameters that are modelled for operations contact water. The parameter values for non-contaminated contact water and non-contact water are modelled to be constant concentrations. In contrast, the water quality at OUT-10 is influenced by the operation of the OWTS, and by the assumed variation rainfall intensity that alters the proportion of non-contaminated contact water in the OWTS effluent at OUT-10. This is illustrated in the model output for EPH plotted in Figure 4-16 that shows an increase in the EPH concentration at OUT-10 when the OWTS is turned on in the model. The influence of the variable rainfall intensity on the non-contaminated contact water flows is reflected in the fluctuating EPH concentrations during the modelled storm event.

The expected and extreme case water quality predictions at OUT-10, and for non-contaminated contact water and non-contact water, meet the federal and provincial WQGs for the protection of MWAL, except pH which exceeds the long-term WQ for the expected case and extreme case (Table 4-13 and Table 4-14). The EPH concentration is modelled to exceed the NOEC value (2.1.2 mg/L) defined in Section 5.4.5.2 during the second and third hours of the modelled storm event. The exceedance of the pH WQG at OUT-10 and for non-contaminated contact water and non-contact water is due to the background condition for non-contact diversion ditch water quality (Section 3.6.3.1) used to model stormwater runoff water quality (Section 4.3.2.2).

The water quality discharged from OUT-01, OUT-02, OUT-04, OUT-06, OUT-11 or OUT-13 is modelled to be similar to non-contact water quality presented in Section 3.6.3.2 (Table 3-23). As outlined in Section 3.6.3.2 (Table 3-19), East Creek discharges through OUT-12 and during operations, the water quality in East Creek is expected to remain within historical ranges.

Table 4-13:
Summary of OUT-10 Predicted Effluent Quality for the Modelled Storm Event

B.C. WQG = British Columbia working and approved water quality guidelines for the protection of marine aquatic life.
CWQG = Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) water quality guidelines for the protection of marine aquatic life. If a WQG for a parameter is provided by each agency, the lowest value is shown in the table.
Bold values exceed one or more of the corresponding B.C., ECCC or CCME long-term WQGs.
Underlined values exceed one or more of the corresponding B.C., ECCC or CCME short-term WQGs.
Grey highlighted values exceed the NOEC (2.12 mg/L) for EPH defined in Section 5.4.5.2.
[1] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. [2] The total ammonia nitrogen B.C. WQG was calculated based on median values for salinity (8.41 ppt), pH (8.05) and temperature (9.46 °C) for CPA stations collected at 0.5 m below surface.
[3] The WQGs for TSS are evaluated assuming the background TSS concentration = 3.0 mg/L (median value of CPA stations 0.5 m below surface).
[4] The B.C. WQG and CWQG for trivalent chromium [Cr(III)] is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the methylmercury concentration and is derived assuming methylmercury is 0.64% of the total mercury concentration (median value from the non-contact diversion ditch dataset).

Table 4-14:
Summary of Non-Contaminated Contact Water and Non-Contact Water Predicted Water Quality for the Modelled Storm Event

B.C. WQG = British Columbia working and approved water quality guidelines for the protection of marine aquatic life.
CWQG = Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) water quality guidelines for the protection of marine aquatic life. If a WQG for a parameter is provided by each agency, the lowest value is shown in the table.
Bold values exceed one or more of the corresponding B.C., ECCC or CCME long-term WQGs.
Underlined values exceed one or more of the corresponding B.C., ECCC or CCME short-term WQGs.
Grey highlighted values exceed the NOEC (2.12 mg/L) for EPH defined in Section 5.4.5.2.
[1] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. [2] The total ammonia nitrogen B.C. WQG was calculated based on median values for salinity (8.41 ppt), pH (8.05) and temperature (9.46 °C) for CPA stations collected at 0.5 m below surface.
[3] The WQGs for TSS are evaluated assuming the background TSS concentration = 3.0 mg/L (median value of CPA stations 0.5 m below surface).
[4] The B.C. WQG and CWQG for trivalent chromium [Cr(III)] is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the methylmercury concentration and is derived assuming methylmercury is 0.64% of the total mercury concentration (median value from the non-contact diversion ditch dataset).

Notes: The NOEC for EPH is defined in Section 5.4.5.2. The long-term WQG for TSS assumes background TSS = 3.0 mg/L (the median value of CPA stations 0.5 m below surface).

Figure 4-16: Predicted Concentration Profile of EPH (C10-C32) and TSS at OUT-10 for the Storm Event Model Condition.

4.3.3.4 Dry Condition Discharge

The OWTS may occasionally be operated during dry conditions to empty the Oily Water Storage Tank to provide storage capacity for a forecast storm event or for routine maintenance. A single 12-hour batch cycle operation is anticipated for these purposes. Under these circumstances, OUT-10 discharge will consist entirely of treated OWTS effluent; therefore, OUT-10 water quality is set equal to OWTS effluent quality source terms. Predicted effluent quality at OUT-10 during dry conditions is summarized in Table 4-15. Outfalls OUT-01, OUT-02, OUT-04, OUT-06, OUT-11 or OUT-13 are not expected to discharge during dry conditions. The OWTS effluent quality for all modelled parameters is tabulated in Appendix 4.3-4.

The predicted OUT-10 effluent quality for the dry condition meets the federal and provincial WQGs except pH and T-Cu in the expected case, and pH, T-Cu and T-Zn in the extreme case. The T-Cu and T-Zn exceedances are due to the modelled loading of particulate-bound metals associated with a TSS concentration of 25 mg/L. The exceedance of the pH WQG is due the background condition of diversion ditch water quality used to model dissolved parameters in stormwater runoff (Section 3.6.3.1 and Section 4.3.2.2).

Table 4-15:

B.C. WQG = British Columbia working and approved water quality guidelines for the protection of marine aquatic life.
CWQG = Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) water quality guidelines for the protection of marine aquatic life. If a WQG for a parameter is provided by each agency, the lowest value is shown in the table.
Bold values exceed one or more of the corresponding B.C., ECCC or CCME long-term WQGs.
<u>Underlined</u> values exceed one or more of the corresponding B.C., ECCC or CCME short-term WQGs.
Grey highlighted values exceed the NOEC (2.12 mg/L) for EPH defined in Section 5.4.5.2.
[1] The approved total ammonia nitrogen B.C. WQG is salinity, pH and temperature dependent; see Tables 26E and 26F in B.C. WQG guidance document. [2] The total ammonia nitrogen B.C. WQG was calculated based on median values for salinity (8.41 ppt), pH (8.05) and temperature (9.46 °C) for CPA stations collected at 0.5 m below surface.
[3] The WQGs for TSS are evaluated assuming the background TSS concentration = 3.0 mg/L (median value of CPA stations 0.5 m below surface).
[4] The B.C. WQG and CWQG for trivalent chromium [Cr(III)] is applied to total chromium results.
[5] The B.C. WQG for total mercury (T-Hg) is dependent on the methylmercury concentration and is derived assuming methylmercury is 0.64% of the total mercury concentration (median value from the non-contact diversion ditch dataset).

4.3.3.5 Conclusions

The POPC screening conducted on OWTS influent identified EPH, pH, TSS, T-Cd, T-Cu, T-Pb, T-Mn, T-Hg, T-V, T-Zn, and benzo(a)pyrene as POPCs. These parameters are carried forward to the POC assessment conducted in Section 5.2.

The lower WQG for pH is exceeded in the modelled expected and extreme conditions for discharges from OUT-01, OUT-02, OUT-04, OUT-06, OUT-10, OUT-11 and OUT-13. This is consistent with the low pH values observed in the monitoring data for non-contact water and creek water quality (Section 3.6.3.1, Table 3-15) at the Project site. Although low pH is a natural condition in freshwater at the site, it is flagged as a POPC and is therefore carried forward to the POC assessment conducted in Section 5.2.

East Creek discharges from OUT-12; the water quality at OUT-12 is expected to be similar to background water quality in East Creek (Table 3-22). Therefore, OUT-12 water quality is not included in the effluent model and is not evaluated for potential environmental effects.

Effluent quality from OUT-10 during dry conditions is predicted to be entirely OWTS effluent and to only occur when the OWTS is occasionally operated. Under these circumstances, the OUT-10 effluent is predicted to meet WQGs or NOEC except EPH, TSS, pH, and T-Cu for the expected and extreme case source terms, and T-Zn for the extreme case (Table 4-16). The T-Cu and T-Zn exceedances are due to the modelled loading of particulate-bound metals associated with a TSS concentration of 25 mg/L. In contrast, during the modelled storm event, OUT-10 effluent is a mixture of OWTS effluent and non-contaminated contact water, and maximum predicted parameter concentrations meet WQGs or NOEC except for EPH. Based on these results, the OUT-10 effluent results that exceed a WQG or NOEC for EPH, TSS, T-Cu or T-Zn are carried forward to the mixing model in Section 4.4 to characterize the OUT-10 initial dilution zone (IDZ) in Howe Sound.

Table 4-16:
Summary of OUT-10 Effluent Quality Maximum Predicted Concentrations for Parameters that Exceed a Threshold Value in One or More Model Scenarios

Parameter	Units	B.C. WQG		CWQG		Dry Condition		Storm Event

4.4 Howe Sound Mixing Model

This section presents the development and results of a mixing model to characterize the OUT-10 effluent mixing zone in Howe Sound. Water quality within the mixing zone is modelled for parameters in OUT-10 effluent that are predicted to exceed threshold values listed in Table 4-17 (*i.e.*, EPH, TSS, T-Cu and T-Zn). Previous analysis conducted in support of the construction WDA application indicates effluent from the Project site rapidly mixes and dilutes in Howe Sound surface waters, and forms the basis for modelling the mixing zone for effluent discharges from OUT-10 during operations.

The mixing model is constructed following the guidance outlined in B.C. Technical Guidance 11, Environmental Management Act, Development and Use of Initial Dilution Zones in Effluent Discharge Authorizations (ENV, 2019). The IDZ is the portion of the mixing zone where WQGs may be exceeded due to the influence from effluent quality. Technical Guidance 11 indicates that "at the edge of an IDZ, the effluent should not cause chronic toxicity in the receiving environment". The mixing model results are combined with the environmental effects assessment in Section 5 to establish the distance from OUT-10 to the edge of the IDZ for the modelled effluent flow scenarios.

4.4.1 Mixing Model Overview

The mixing zone model utilized for this assessment is CORMIX (v.11). The CORMIX model is a software system for the analysis, prediction, and design of aqueous toxic or conventional pollutant discharges into diverse water bodies (Doneker and Jirka, 2021), and is recognized and accepted by professionals and regulators as appropriate for characterizing the initial dilution zone (IDZ) of receiving waterbodies. The major emphasis of the system is on the geometry and dilution characteristics of the initial mixing zone, including compliance with regulatory constraints as well as to predict the behavior of the discharge plume at larger distances. CORMIX is selected as the modelling platform based on the recommendations provided in Appendix C of Technical Guidance 11 (ENV, 2019). The modelling is conducted with a steady state model which assumes steady tidal and ambient current velocities, as well as constant and continuous effluent discharge flow rates. The steady state model quantifies an equilibrated effluent plume, whereby the spatial distribution and effluent concentrations do not vary with time.

The influence of the FSTs at the Marine Storage Facility on the mixing of the effluent plume is also taken into consideration. CORMIX allows for two lateral boundary (bank) conditions to characterize the receiving channel: 1) bounded, referring to a channel that is constrained on both sides by a bank such as rivers, streams or other narrow watercourses, or 2) unbounded, referring to water bodies which are, for practical purposes, constrained only on one side such as lakes, wide estuaries, and coastal areas. The FST, located approximately 100 m from the shoreline onto which OUT-10 discharges, is expected to behave as a lateral boundary for the water intermediate to the shoreline and length of the facility. This is illustrated in Figure 4-17. The ambient current is modelled to flow from the northeast to the southwest based on findings by Buckley (1977), which also show that the current direction by depth may be affected by estuarine circulation system pattern of outflowing surface layer compensatory inflow. Additionally, the current direction may also be temporarily reversed due to tidal currents.

Based on the location of OUT-10 relative to the FST, the bounded section is approximately 100 m as shown in Figure 4-17. Once the plume has travelled more than 100 m, it is no longer constrained by the lateral boundary formed by the FST and is thereafter assumed to behave as if under unbounded channel conditions. To represent this specific configuration, OUT-10 discharge is modelled using a bounded condition for the first 100 m from OUT-10 and an unbounded condition beyond that distance. If the ambient current direction reverses due to tidal currents, the lateral boundary (*i.e.*, the bounded channel) becomes approximately 300 m in length.

Figure 4-17: Bounded and Unbounded Mixing Zone Sections for OUT-10 Discharge.

4.4.2 Mixing Model Scenarios

The mixing model evaluates the plume characteristics and effluent concentration in the Howe Sound mixing zone for two scenarios: 1) during a storm event when peak discharge rates are expected to be encountered, and 2) during dry conditions when the only input to OUT-10 discharge is treated effluent from the OWTS. The storm event scenario is based on the peak discharge rate (290 L/s) during a 1:2 year 24-hour storm event from OUT-10 (Section 4.3.3.1), when outflows are dominated by stormwater runoff from non-contaminated areas relative to OWTS discharge. In contrast, the dry condition scenario represents discharge when there is no stormwater runoff and the OWTS is the only source of effluent at OUT-10. This occurs when the OWTS is operated to reduce the volume of water stored in the Oily Water Storage Tank. The mixing model assumes OUT-10 flows during the dry conditions will equal the maximum OWTS treatment flow rate of 8.3 L/s.

In addition to the two effluent flow scenarios, modelling is also undertaken using three wind speeds: low (2 m/s), moderate (5 m/s) and high (10 m/s). Previous analysis and modelling (Lorax, 2024a) demonstrates that wind speed is a sensitive model parameter that significantly influences mixing and plume characteristics. Given the sensitivity of wind speed in the mixing model, the low, moderate and high wind speeds are coupled with the discharge rates from each of the effluent flow scenarios to evaluate and bound the effects of wind on mixing model predictions.

4.4.3 Mixing Model Inputs

CORMIX requires numerous inputs defining the physical and chemical properties of the receiving environment (Howe Sound), the discharge rate, current velocity, effluent water quality, and the geometry of the discharge outlet structure. The list of mixing model inputs and associated values are provided in Table 4-17. The data analysis conducted for parameter estimation, along with a detailed description of each parameter, are documented in Lorax (2026).

The median Howe Sound water quality collected from CPA stations at 0.5 m below surface (Table 3-30) were used as background water quality. The effluent concentrations of TSS, EPH, T-Cu and T-Zn shown in Table 4-16 are used as inputs for the storm event and dry condition effluent quality.

Table 4-17:
Summary of CORMIX Model Inputs

Source	Model Parameter	Value
Howe Sound (Receiving Environment)	Average Depth	45 m
	Pycnocline Depth	10 m
	Water Density Above Pycnocline	1011.4 kg/m^3
	Water Density Below Pycnocline	1023.21 kg/m^3
	Background Salinity	15 PSU (above pycnocline)
		30 PSU (below pycnocline)
	Manning's Coefficient	0.025
	Appearance	Uniform
	Wind Speed	2, 5 or 10 m/s
	Depth at Discharge Location	0 m
	Ambient Current Velocity	1.5 cm/s
	TSS Concentrations	3 mg/L
Effluent and Discharge Channel Parameters	Water Temperature	10 ºC
	Discharge Channel Width	1 m
	Discharge Channel Depth	0.5 m
	Discharge Channel Bottom Slope	18º
	Channel Angle to Howe Sound	90º
OUT-10 Discharge Flow Rate	Discharge Flow Rate (Storm Event)	290 L/s (peak flow)
	Discharge Flow Rate (Dry Condition)	8.3 L/s (OWTS maximum)

4.4.4 Mixing Model Results

The results of the steady state mixing model predictions for storm event and dry condition discharges from OUT-10 are presented in this section. The model assumes steady state (*i.e.*, constant) effluent discharge characteristics, receiving environment and climate conditions. As discussed in Section 4.4.1, the mixing of OUT-10 discharge to Howe Sound is modelled to reflect the expected influence of the FST on the receiving channel conditions (Figure 4-17). Therefore, the mixing model accounts for the conditions produced by the physical infrastructure. Additionally, for each effluent flow scenario, effluent mixing and water quality predictions are generated for low (2 m/s), moderate (5 m/s) and high (10 m/s) wind cases given the sensitivity of the steady state model to wind speed and the variability expressed in measured wind speed data (Lorax, 2026). Figures illustrating the mixing model results are shown at the end of Section 4.4.4.1 and the end of Section 4.4.4.2.

4.4.4.1 Storm Event Discharge

The predicted OUT-10 effluent mixing in Howe Sound during the modelled storm event is presented as a mixing ratio in Figure 4-18. The mixing ratio prediction represents the relative volume of Howe Sound water that mixes with a unit volume of effluent along the axis of maximum concentration as the plume extends away from the OUT-10 discharge location. The axis of maximum concentration defines the point of highest concentration within the effluent plume at any given distance from the outfall. The lowest mixing ratio values and highest concentrations occur along the axis of maximum concentration. Lateral effluent dispersion away from the axis of maximum concentration increases the volume of Howe Sound water relative to the volume of effluent, resulting in lower parameter concentrations relative to concentrations modelled for the axis. The mixing model combines the mixing ratio with effluent and background water quality to calculate a parameter concentration as a function of distance from OUT-10, and accounts for lateral dispersion from the axis of maximum concentration when applying the mixing ratio.

In general, the mixing ratio is expected to increase with distance in an unbounded receiving environment due to plume spreading induced by the ambient current and wind turbulence. However, under bounded conditions, the dilution ratio may be limited when the plume becomes fully mixed between the shore and lateral boundary. The effect of the FST bounded channel (100 m from OUT-10 outlet) on effluent mixing is shown in Figure 4-18, whereby the mixing ratio is constant between approximately 55 to 100 m from the OUT-10 outlet. This indicates that the effluent plume exhibits complete transverse lateral mixing within the bounded channel at approximately 55 m from the outlet. Additionally, the plume depth ranges from 0.75 m to 0.85 within the bounded section for all wind cases. The low and moderate wind case plumes remain isolated to the upper 1 m deep surface layer in the

unbounded far-field region, whereas the high wind exhibits additional vertical mixing, with plume mixed downwards to a 2 m depth.

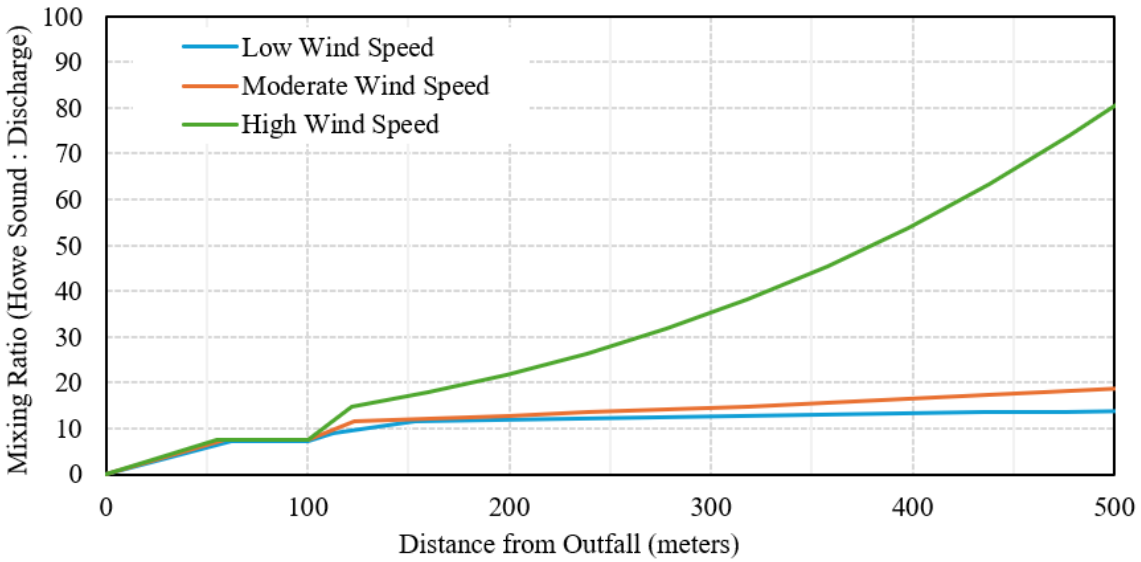

Figure 4-18: Volume Mixing Ratio for the Storm Event OUT-10 Effluent Discharge Rate Under Low, Moderate and High Wind Speeds.

During temporary current reversal, the effluent mixing ratio in the upstream bounded channel (from 55 m upstream to 300 m upstream) will be similar to the constant ratio expressed in the 55 m to 100 m downstream bounded section as shown in Figure 4-18. The plume is expected to reach complete lateral mixing within 55 m of the bounded channel regardless of current direction. Once complete lateral mixing is achieved, the mixing ratio will remain a constant value until the plume exits to an unbounded section.

The mixing ratio within the unbounded channel for high wind case is considerably larger than the low and moderate wind cases. This is related to the greater plume dispersion due to increased wind turbulence, which causes the effluent to mix with a greater volume of water in Howe Sound.

While varying wind speeds exhibit substantially different mixing ratios in the unbounded receiving environment, the mixing ratio for all wind cases is similar in the bounded section. This is likely because wind has lesser effect in near-field mixing but critically affects plume behavior in the far field (Doneker and Jirka, 2021). Near-field is the region of a receiving water where the discharge momentum flux, buoyancy and outlet geometry are the dominant influence on the trajectory and mixing of effluent, whereas far-field is the region of the receiving water where buoyant spreading motions, wind-induced turbulent mixing and passive diffusion control the trajectory and mixing of the effluent plume (Doneker and Jirka, 2021). Since the plume source characteristics are the same for all wind speeds, the

plume mixes similarly under all wind cases within the near-field given the marginal influence of wind speed in this region.

As illustrated in Figure 4-19 and Figure 4-20, predicted effluent plume concentrations for the storm event expected and extreme case effluent quality meet WQGs at the point of discharge for TSS, T-Cu and T-Zn, whereas the EPH concentration is slightly above the NOEC value. The concentrations of all parameters decrease sharply in response to dilution from the Howe Sound background ambient waters until the plume is completely mixed within the bounded section, approximately 50 to 60 m from OUT-10. After the plume exits the bounded section and enters the unbounded receiving environment, the predicted concentrations begin to decrease again, although more gradually compared to the initial rate of decrease exhibited within the first 50 to 60 m of the bounded section.

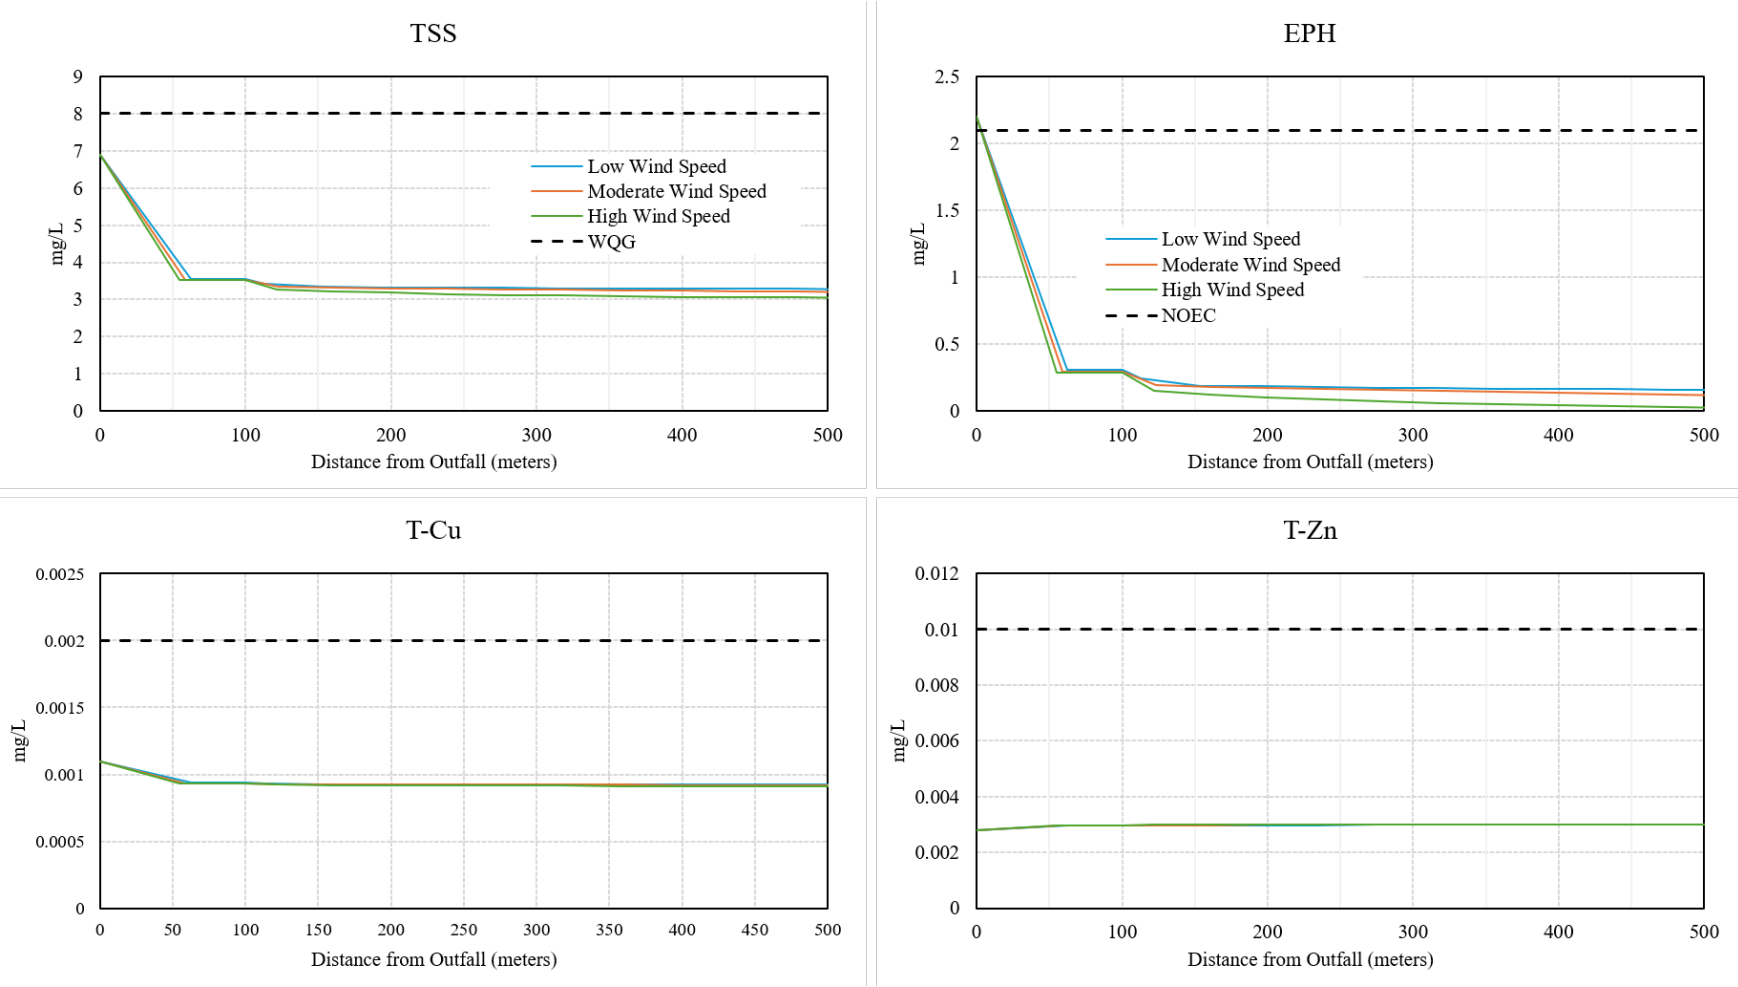

Figure 4-19: Predicted Concentrations of TSS, EPH, T-Cu and T-Zn along the Effluent Plume Axis of Maximum Concentration as a Function of Distance from OUT-10 for Storm Event Expected Case Effluent Quality and Discharge Rate (100 m Bounded Channel).

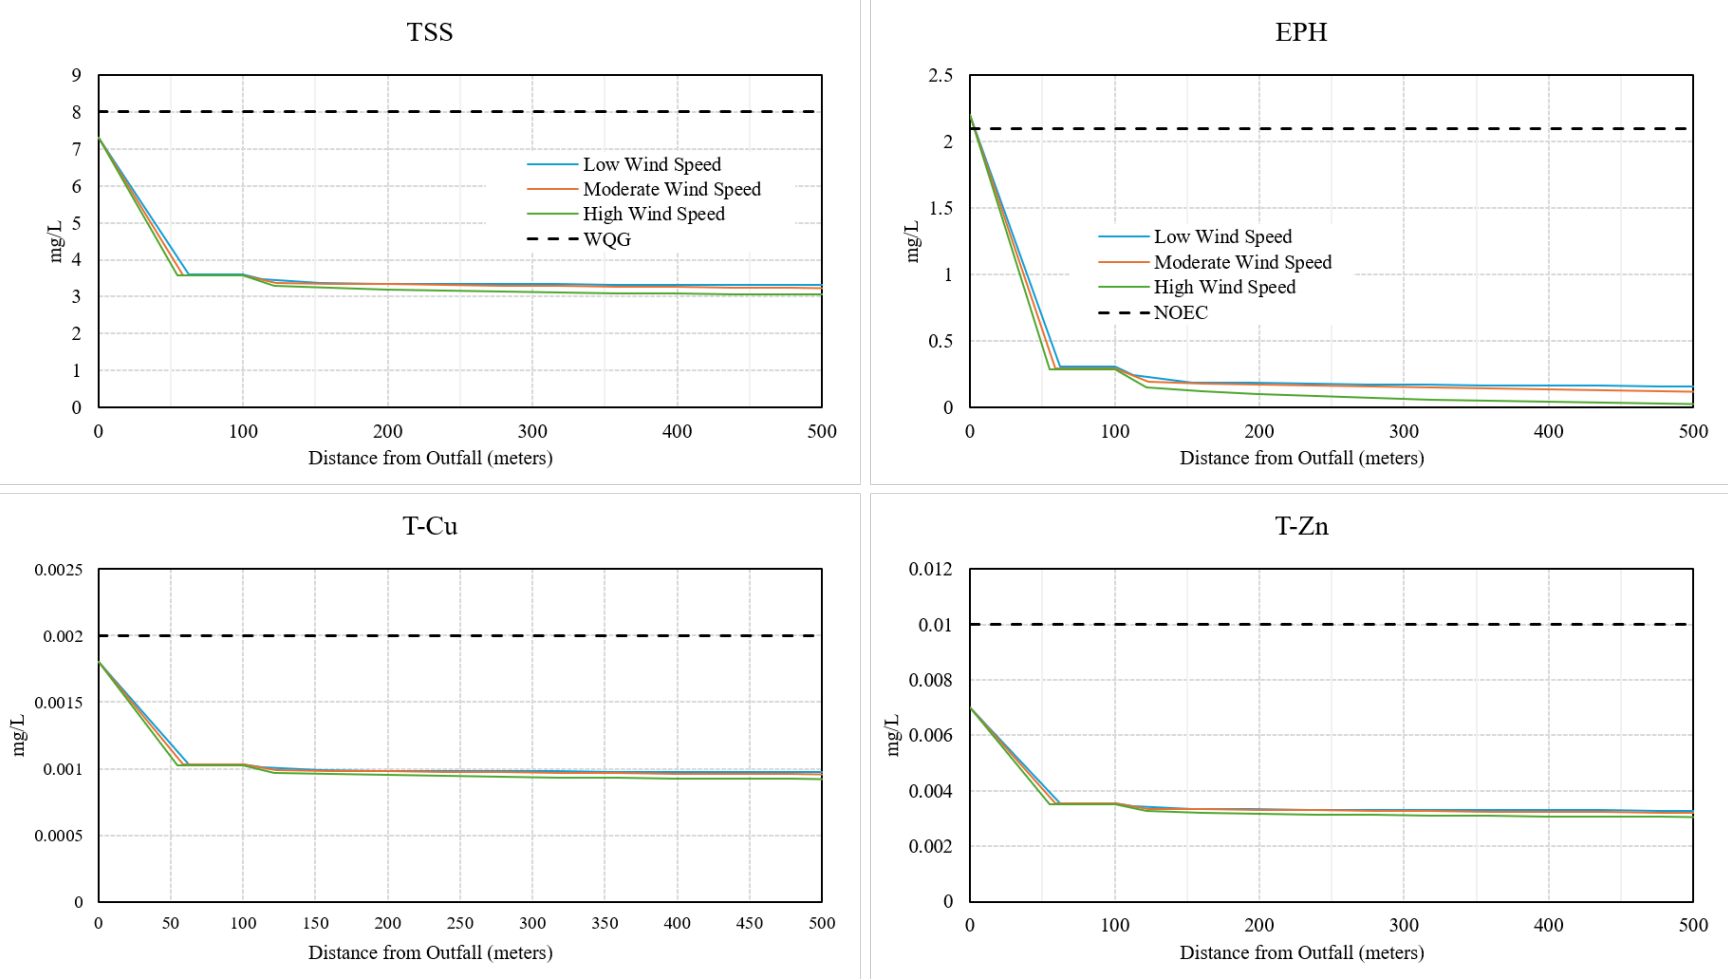

Figure 4-20: Predicted Concentrations of TSS, EPH, T-Cu and T-Zn along the Effluent Plume Axis of Maximum Concentration as a Function of Distance from OUT-10 for Storm Event Extreme Case Effluent Quality and Discharge Rate (100 m Bounded Channel).

4.4.4.2 Dry Condition Discharge

The effluent model assumes that dry condition discharges from OUT-10 will consist entirely of OWTS effluent. The effluent concentrations of EPH, TSS and T-Cu for the expected and extreme case source terms, and T-Zn for the extreme case (Table 4-16) are predicted to exceed WQGs and the NOEC for EPH (Table 4-16). Therefore, the mixing zone for these parameters is evaluated. The Howe Sound mixing model assumes dry condition OUT-10 effluent will be discharged at 8.3 L/s, the maximum flow from the OWTS. Graphs referenced in the following discussion are presented at the end of this section (Figure 4-21 through Figure 4-26).

The predicted effluent mixing ratios increase with distance from the point of discharge, and, as shown in Figure 4-21, moderate (5 m/s) and high (10 m/s) winds result in higher mixing ratios compared to the low wind case (2 m/s) along the entire axis of the effluent plume. This difference in mixing ratios is due to an increase in the effluent plume transverse lateral dispersion and vertical mixing depth at the top of the Howe Sound water column as a function of wind speed, and this in turn increases the total volume of Howe Sound water that is available for mixing with effluent. The mixing ratio profile along the axis of maximum concentration indicates that the effluent plume does not achieve complete lateral mixing (*i.e.* uniform mixing ratio between FST and shoreline) within the bounded channel (100 m). However, the high wind speed case, lateral mixing is nearly complete at the edge of the bounded section.

The rate and depth of vertical mixing vary for each wind speed in the dry condition model scenario. In the low wind case, the rate of vertical mixing is less than in moderate or high wind cases. The predicted plume thicknesses vary based on wind speed, ranging from 0.2 to 3.9 m within a near-field mixing zone that range from 105 to 245 m from the discharge location (refer to Table 4-18). The plume is completely mixed to the top of the pycnocline (*i.e.,* 10 m depth) within the far-field for the moderate and high wind cases but remains isolated to the surface layer in the low wind scenario.

Table 4-18:
Mixing Model Results for the Extent and Thickness of the Effluent Plume in the Near-Field for the 2, 5, and 10 m/s Wind Cases

Wind Speed (m/s)	Near-Field Extent (m)	Near-Field Plume Thickness (m)
2	215	0.2
5	245	1.4
10	105	3.9

In a current reversal scenario, the bounded channel is 300 m long, and the effluent plume achieves complete transverse lateral mixing at 200 m and 250 m, for the low and moderate wind speed cases, respectively. This is illustrated in Figure 4-22. Under these conditions, the effluent mixing ratio and plume concentrations would remain constant from the point of complete lateral mixing (200 m, 250 m, and 100 m, for low, moderate and high wind) to the end of the bounded section (*i.e.*, approximately 300 m from the OUT-10. The respective plume thickness for low, moderate and high wind cases within the bounded section is approximately 0.2 m, 3.33 m and 5.3 m. Thereafter, when the plume enters the unbounded channel, mixing with Howe Sound resumes and the axis of maximum concentration slowly declines with distance from the outfall.

The influence of wind induced mixing is reflected in the predicted effluent plume concentrations. This is shown in Figure 4-23 (expected case) and Figure 4-24 (extreme case) for the 100 m bounded channel. The concentration profiles for current reversal with the 300 m bounded channels are shown in Figure 4-25 (expected case) and Figure 4-26 (extreme case). For the 100 m and 300 m bounded channels, the effluent plume axis of maximum concentration predicted for the moderate and high wind cases approach Howe Sound background concentrations less than 100 m from OUT-10, compared to less than 500 m for the low wind speed case. For all modelled wind speeds, the concentrations of EPH, TSS, T-Cu and T-Zn decrease rapidly with distance from the outfall, and all parameters meet WQGs or NOEC along the axis of maximum concentration within approximately 80 m of OUT-10, for the expected and extreme case effluent quality.

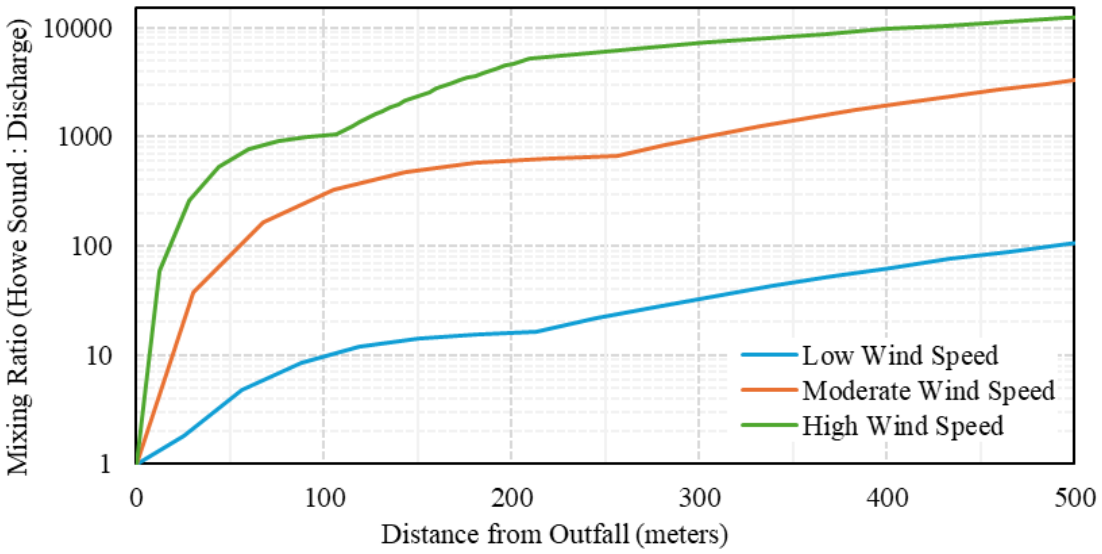

Figure 4-21: Volume Mixing Ratio for the Dry Condition OUT-10 Effluent Discharge Rate Under Low, Moderate and High Wind Speeds (Y-axis is log scale).

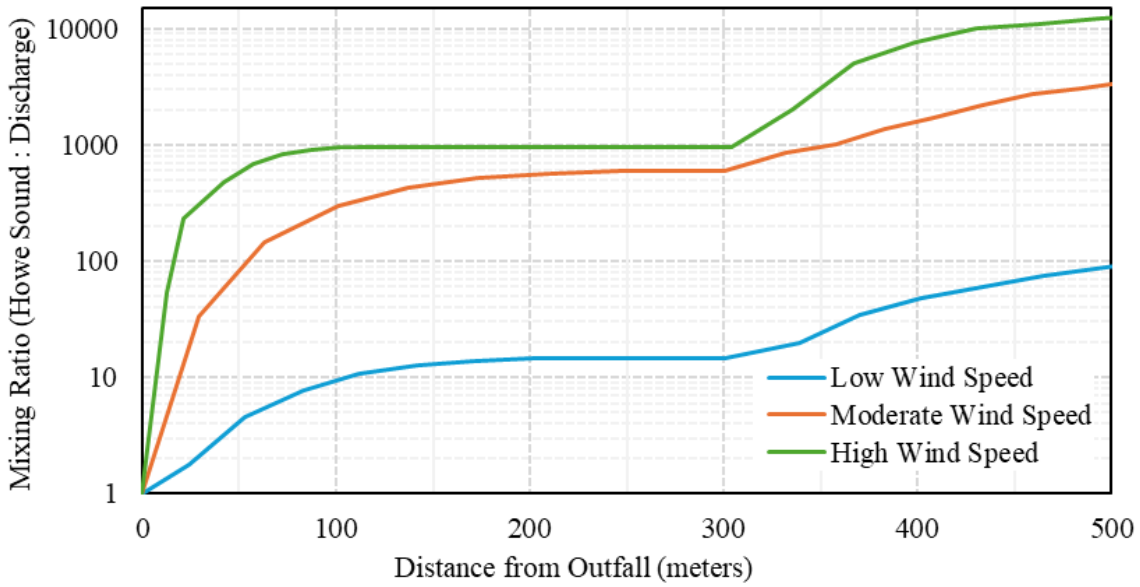

Figure 4-22: Volume Mixing Ratio for the Dry Condition OUT-10 Effluent Discharge Rate During Current Reversal Scenario Under Low, Moderate and High Wind Speeds (Y-axis is log scale).

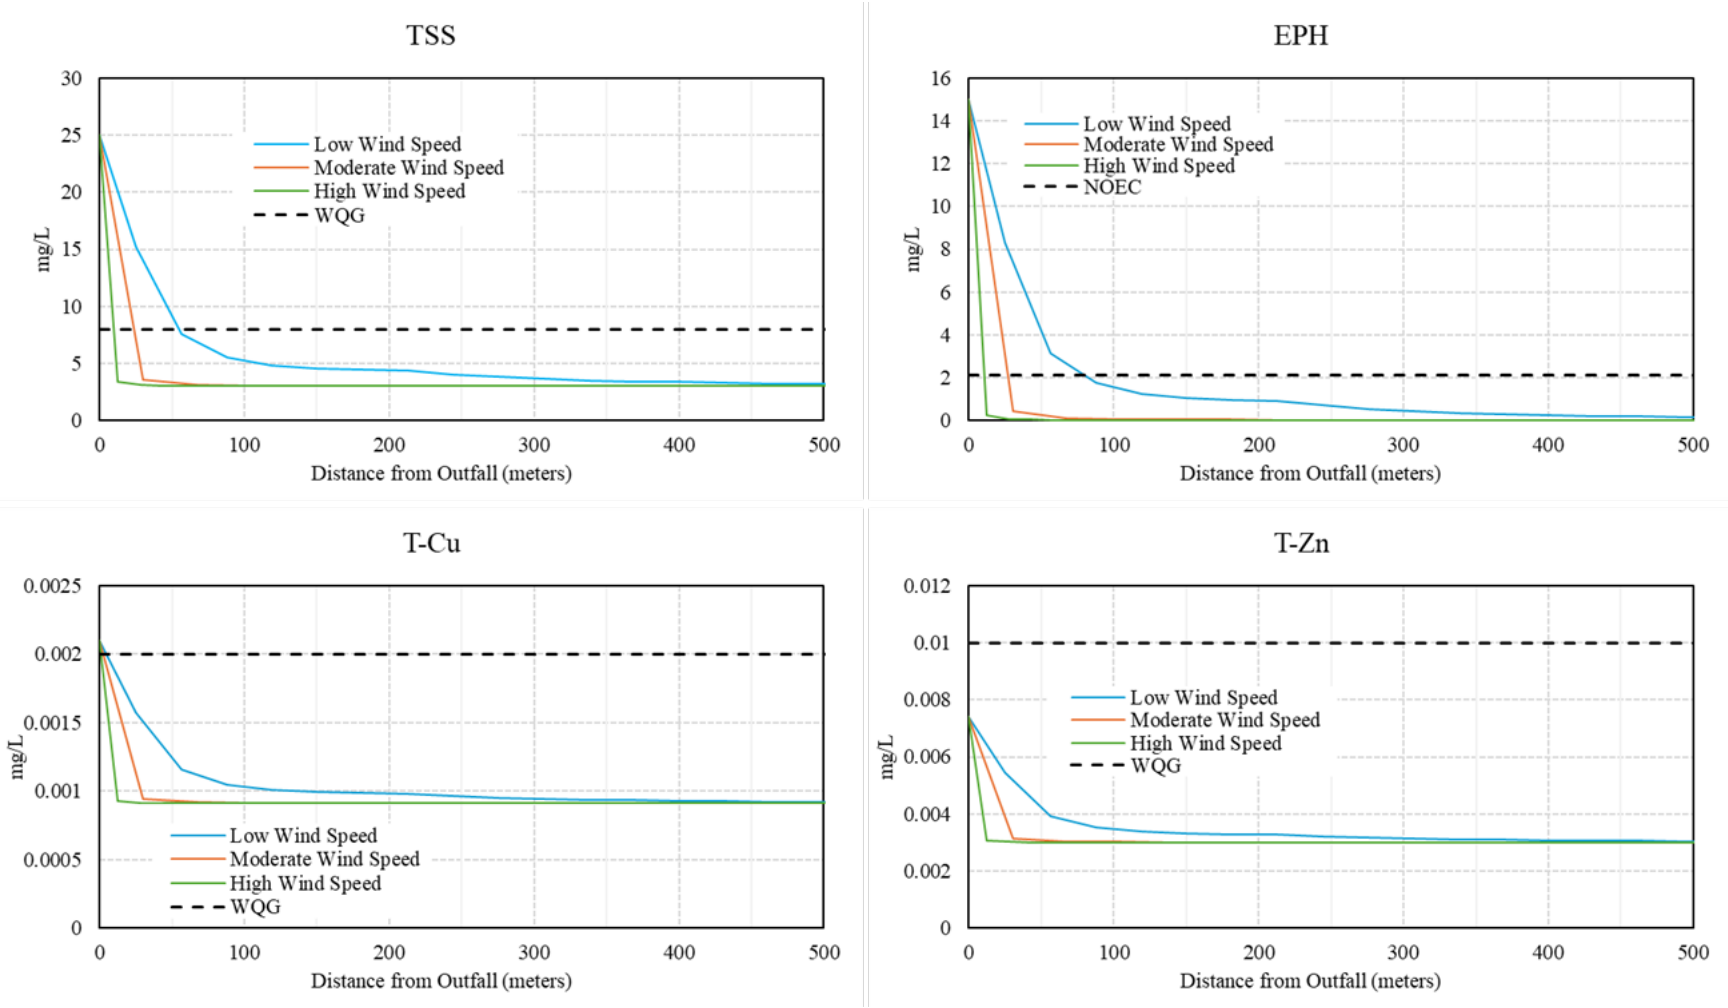

Figure 4-23: Predicted Concentrations of TSS, EPH, T-Cu and T-Zn along the Effluent Plume Axis of Maximum Concentration as a Function of Distance from OUT-10 for Dry Condition Expected Case Effluent Quality and Discharge Rate (100 m Bounded Channel).

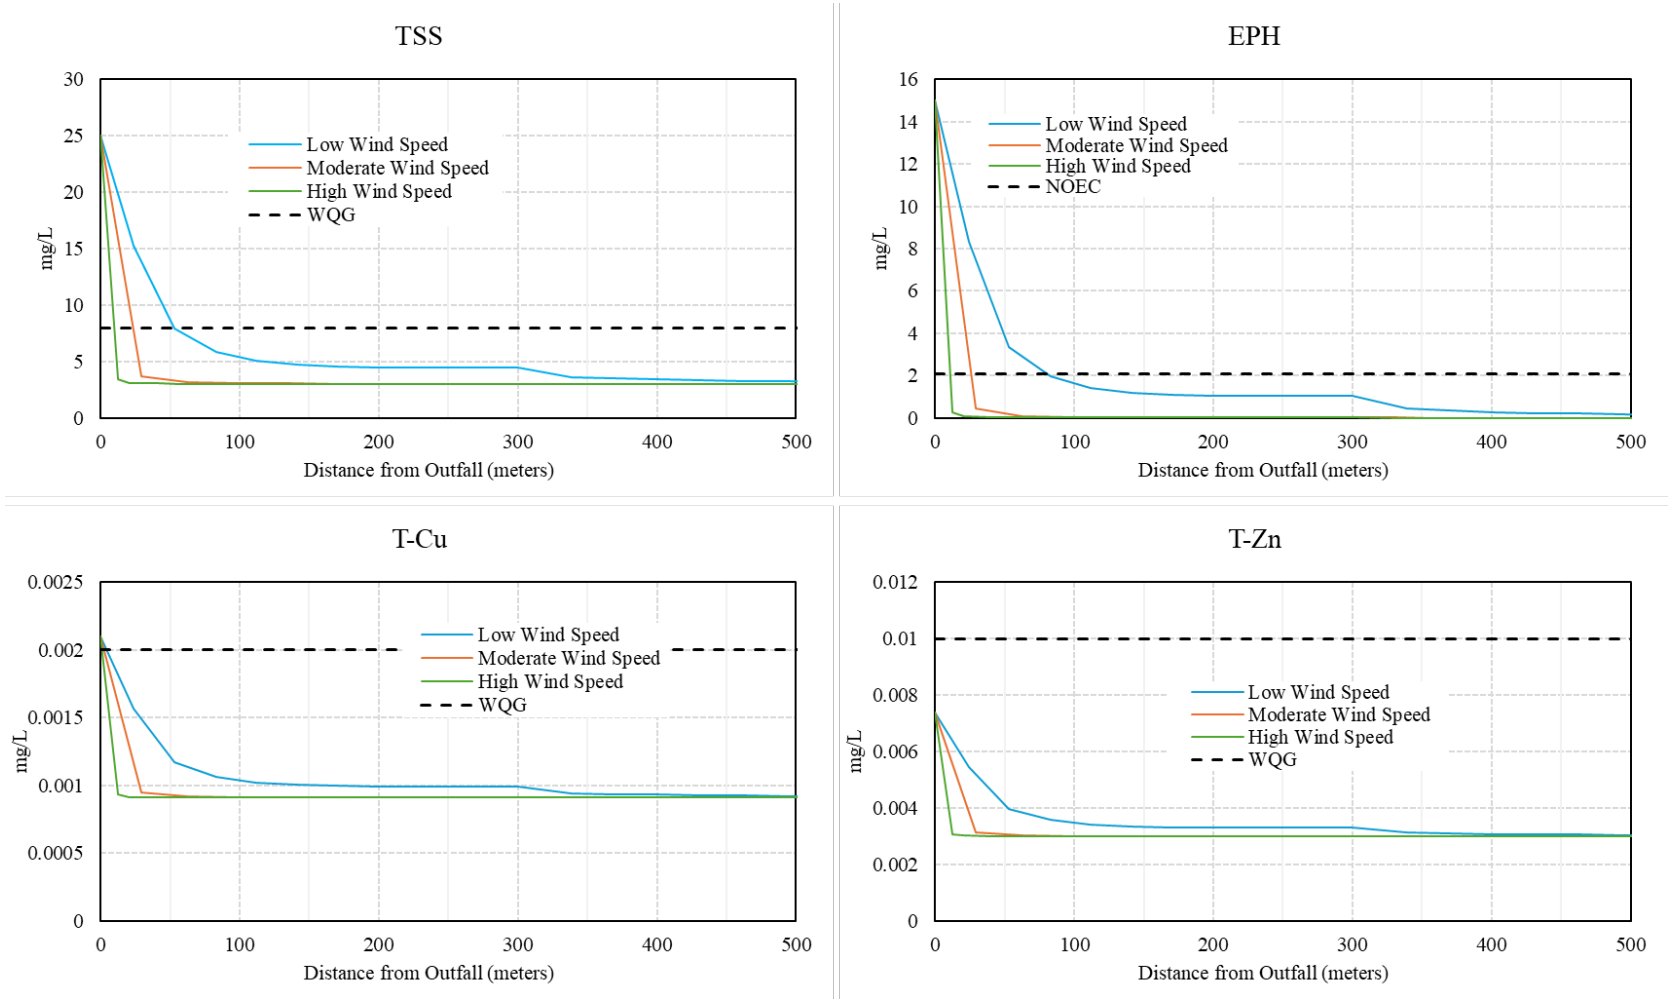

Figure 4-25: Predicted Concentrations of TSS, EPH, T-Cu and T-Zn along the Effluent Plume Axis of Maximum Concentration as a Function of Distance from OUT-10 for Dry Condition Expected Case Effluent Quality and Discharge Rate (Current Reversal, 300 m Bounded Channel).

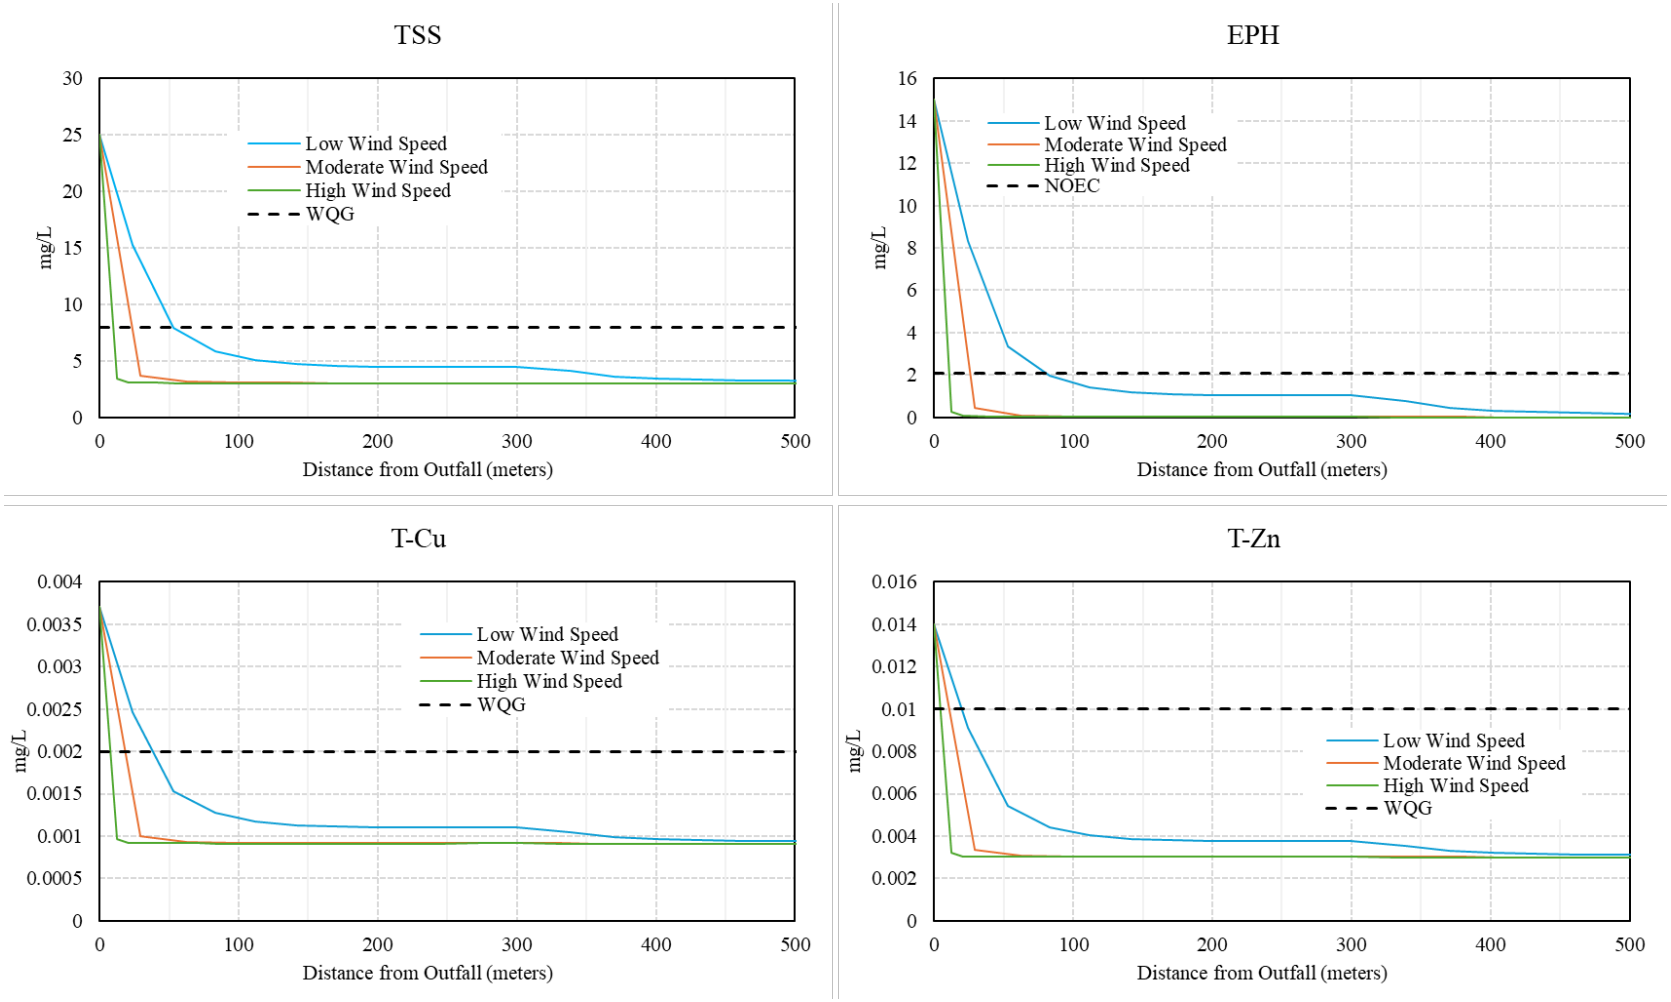

Figure 4-26: Predicted Concentrations of TSS, EPH, T-Cu and T-Zn along the Effluent Plume Axis of Maximum Concentration as a Function of Distance from OUT-10 for the Dry Condition Extreme Case Effluent Quality and Discharge Rate (Current Reversal, 300 m Bounded Channel).

4.4.5 Conclusions

The CORMIX steady state mixing model predicts the OUT-10 mixing zone is a shallow effluent plume that mixes with Howe Sound surface waters. The extent of the plume is predicted to vary with wind speed and effluent velocity. Effluent discharge from OUT-10 is primarily associated with rainfall (*i.e.*, stormwater runoff) or OWTS maintenance (*i.e.*, OWTS effluent only) and is therefore intermittent rather than continuous.

The effluent mixing ratios for the dry condition discharge (Figure 4-21) are considerably greater than the storm event (Figure 4-18) for all wind cases. This is related to the difference in discharge rates between the two scenarios. The higher discharge rate modelled for the storm event (290 L/s compared to 8.3 L/s for dry conditions) results in a lower mixing ratio due to the significantly larger volume of effluent that is discharged. As a consequence of the channel boundary imposed the FST, the storm event mixing model predicts full mixing across the channel width occurs at approximately 50 to 60 m from OUT-10, and the effluent plume remains fully mixed to approximately 0.75 m to 0.85 m depth until the unbounded channel is reached, approximately 100 m from OUT-10, or approximately 300 m in a reverse current condition.

The dry condition effluent plumes for all modelled wind speeds do not attain a fully mixed condition across the 100 m channel width within the FST bounded section (Figure 4-17). Within the bounded section, the plume depth is 0.2 m, 1.44 m and 3.90 m for the low, moderate and high wind cases, respectively. However, if the current is reversed, the low, moderate and high wind case plumes attain complete lateral mixing at 200 m, 250 m and 105 m, respectively, from the OUT-10. Additionally, under current reversal conditions, the mixing depth within the bounded channel (300 m) ranges from approximately 0.2 m to 5.3 m, with deeper mixing occurring as wind speed increases.

The predicted water quality along the effluent plume axis of maximum concentration is used to estimate the extent of the overall mixing zone for three wind speeds, two effluent flow rates, and two sets of effluent quality. The model results indicate the distance from OUT-10 to an effluent plume concentration threshold value that is protective of chronic effects to MWAL ranges from approximately 20 to 80 m for various modelled scenarios, regardless of current direction (Figure 4-23 through Figure 4-26). Based on these results, it is recommended the edge of the IDZ be set to 100 m from OUT-10 (Figure 4-23 and Figure 4-24).

5. Environmental Effects

5 Environmental Effects

5.1 Introduction

This section provides an assessment of potential effects from modelled effluent discharge at OUT-10 to potential receptors in Howe Sound (Figure 5-1). Aquatic life is the most sensitive receptor to changes in water quality, as reflected by the more stringent B.C. WQGs for the protection of aquatic life compared to those for wildlife and livestock. It is unlikely that terrestrial wildlife will use Howe Sound as a source of drinking water, while aquatic life is directly exposed to marine water quality. Therefore, the effects assessment focuses on aquatic life as the most likely receptor for potential adverse effects from changes to water quality.

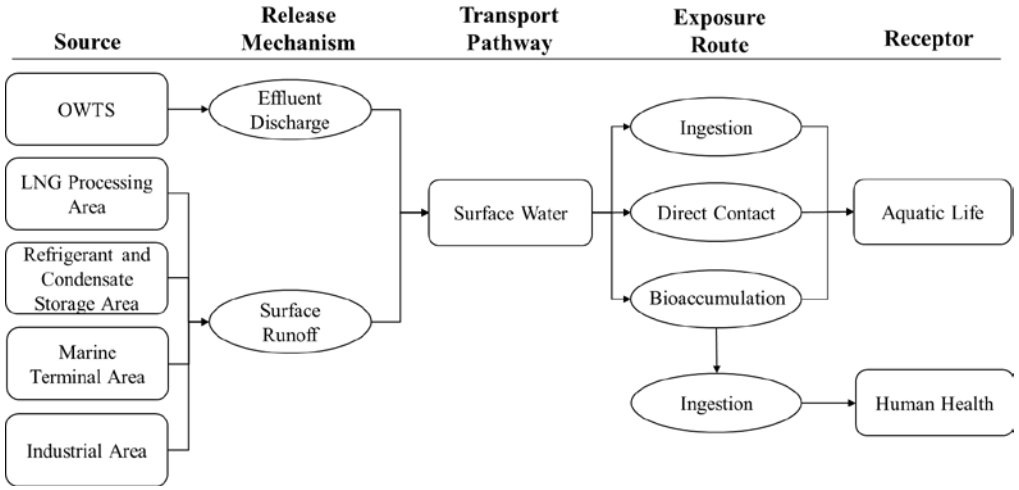

Figure 5-1: Conceptual Site Model of Aqueous Contaminant Transport to Receptors

Treated contact water from the OWTS will be discharged from OUT-10 through the non-contaminated contact water system, along with stormwater runoff from non-contaminated areas. The discharge volumes will vary depending primarily on precipitation and associated stormwater runoff. Two precipitation conditions are modelled for OUT-10 in the effluent and mixing models (Section 4.3 and Section 4.4, respectively): 1) during a 2-year return period, 24-hour storm event, and 2) when the OWTS is operated during dry conditions (*i.e.*, no precipitation). While the OWTS is designed to treat stormwater, it will be batch operated infrequently for maintenance or to empty the Oily Water Storage Tank in advance of a rainfall event. Under dry conditions, OUT-10 effluent is modelled to be composed of 100% OWTS treated effluent. During storm events, OUT-10 effluent is modelled to be a mixture of OWTS treated effluent and non-contaminated contact water.

At OUT-10, the model scenario for dry conditions (*i.e.*, 100% OWTS treated effluent) is evaluated first since it has higher effluent predictions and higher potential to cause adverse effects in the receiving environment than the storm event modelled concentrations. Effluent quality at OUT-10 during a storm event is only evaluated if potential adverse effects are identified under dry conditions.

The effects assessment evaluates two source term scenarios incorporated in the Effluent Model (as described in Section 4.3.2):

1) source terms derived from the median concentrations from water quality monitoring results (expected case); and
2) source terms derived from the 90th percentile concentrations from water quality monitoring results (extreme case).

The effects assessment evaluates three mixing scenarios incorporated in the IDZ receiving environment model (as described in Section 4.4):

1) high wind speed (10 m/s);
2) moderate wind speed (5 m/s); and
3) low wind speed (2 m/s).

5.2 Parameters of Concern

As described in Section 4.3.3.2, water quality model results are screened to identify POPCs and POCs to aquatic life in the marine receiving environment. A POPC is defined as any parameter predicted to be greater than 80% of a threshold value in untreated effluent, while a POC is a POPC that requires further assessment to determine its risk to the environment (ENV, 2024). The lowest applicable federal or B.C. WQGs for the protection of MWAL are used to screen the expected case and extreme case model results. Parameters with the potential to occur from site operations, including those without WQGs (*e.g.*, EPH) are categorized as POPCs based on the BATA (MDR, 2026b or Appendix 4.2-1) and included in the effects assessment.

The screening of operations model results for untreated effluent quality at OUT-10 (Table 4-12, Section 4.3.3.2) identified the following POPCs: EPH, pH, TSS, T-Cd, T-Cu, T-Pb, T-Mn, T-Hg, T-V, T-Zn, and benzo(a)pyrene for the expected case and extreme case scenarios. These POPCs are modelled to be associated with TSS except for pH, which reflects natural background conditions. As a conservative approach, the above-mentioned POPCs at OUT-10 are all considered POCs in the water quality model and carried forward to an effects assessment.

5.3 Effects Assessment Approach

Effects assessments are conducted for the POCs identified in Section 5.2 using both expected case and extreme case model predictions to address the uncertainty associated with source term derivation (Section 4.3.2). The expected case represents the mid-point parameter concentrations under normal conditions. An upper range of potential concentrations is represented by the extreme case and is considered significantly less likely to occur than expected case, and to occur infrequently.

Both long-term (chronic) and short-term (acute) WQGs are considered for the effects assessment. Concentrations that are greater than a WQG do not imply that unacceptable risks are present, but that the potential for adverse effects may be increased and additional investigation and monitoring may be warranted.

Definitions and criteria outlined in the B.C. Environmental Assessment Office's Effects Assessment Policy (EAO, 2020) are followed for the effects assessment. Residual effects, defined as those effects remaining after the implementation of mitigation measures, are assessed for POCs identified in the modelled effluent discharged from OUT-10. Residual effects are characterized based on the ecological context, magnitude, spatial extent, duration, frequency, and reversibility of an effect. These criteria are used to determine the likelihood of OUT-10 effluent to cause potential adverse effects to aquatic life in the marine receiving environment.

The Howe Sound mixing model (Section 4.4) predicts the characteristics and extent of the OUT-10 effluent mixing zone in Howe Sound. The effluent plume is predicted to mix within the freshwater influenced surface layer of Howe Sound as it extends from OUT-10. The edge of the IDZ is defined to extend up to approximately 80 m from the outlet. As noted in Section 4.4.5, the edge of the IDZ is recommended to be set to 100 m. Therefore, the size of the IDZ is set to 100 m for the effects assessment.

Ecological context of the receiving environment is characterized as low, medium, or high based on the aquatic habitat and species that may be exposed to elevated concentrations of POCs.

- Low: no unique attributes or low ecological value.
- Medium: sensitive habitats or species with some ecological value.
- High: sensitive habitats or species with high ecological value.

Magnitude is characterized as low, medium, or high based on the modelled concentrations of POCs in the receiving environment relative to long-term WQGs for the protection of marine aquatic life. The following characterization of magnitude is based on the method

generally used to develop marine WQGs, which applies a factor of 2 to 10 to a toxicity value to establish guidelines that are protective of all marine life.

- Low: concentrations less than or equal to the long-term WQG at the edge of the IDZ.
- Medium: concentrations greater than the long-term WQG but less than or equal to two times the guideline at the edge of the IDZ.
- High: concentrations greater than two times the long-term WQG at the edge of the IDZ.

Spatial extent is characterized as local or regional.

- Local: effluent discharge is predicted to result in parameter concentrations that are greater than WQGs only within the IDZ.
- Regional: effluent discharge is predicted to result in parameter concentrations that are greater than WQGs beyond the IDZ.

Duration is characterized as short-term, medium-term, or long-term.

- Short-term: an effect that lasts less than or equal to 96 hours.
- Medium-term: an effect that lasts more than 96 hours and less than 30 days.
- Long-term: an effect that lasts 30 days or more.

Frequency is characterized as rare, sporadic, or continuous based on how often marine aquatic life is expected to be exposed to concentrations that are greater than long-term WQGs.

- Rare: an effect that occurs once a year during operations.
- Sporadic: an effect that occurs intermittently during operations.
- Regular: an effect that occurs regularly during operations.

Reversibility is characterized by the length of time that it would take for POC concentration increases to be reversed after effluent discharge is ceased.

- Reversible short-term: concentration decreases to below its long-term WQG relatively quickly (*i.e.,* days).
- Reversible long-term: concentration decreases to below its long-term WQG after months or years.
- Irreversible: concentration permanently remains above it long-term WQG.

Confidence and uncertainties associated with the residual effects characterization are discussed for each POC.

5.4 Residual Effects Assessment

5.4.1 pH

The modelled pH in effluent discharged from OUT-10 is outside of the long-term WQG range (7.0 – 8.7) for the expected case (pH 6.6) and extreme case (pH 6.1) scenarios (Table 4-16). The low modelled pH represents background conditions for non-contact diversion ditch water quality, which was used to model stormwater runoff water quality. As discussed in Section 3.6.3.1, pH is mildly acidic to circumneutral at creek background water quality stations and in non-contact water that discharge to Howe Sound from diversion ditches. Given the natural background conditions observed in Woodfibre Creek (pH 5.63 to 6.49), Mill Creek (pH 5.25 to 8.40), East Creek (pH 6.26 to 7.38), and non-contact water (pH 5.60 to 8.20), the modelled pH in OUT-10 effluent (6.6 for expected case and 6.1 for extreme case) is not expected to have adverse residual effects on the receiving environment.

5.4.2 Mitigated Parameters of Concern

Parameters of concern are identified from untreated effluent quality model results (Section 4.3.3.2). Among the POCs carried forward for effects assessment, the following parameters are modelled to meet WQGs in treated effluent discharged from OUT-10 under both the expected case and extreme case scenarios (Table 4-15):

- T-Cd;
- T-Pb;
- T-Mn;
- T-Hg;
- T-V; and
- Benzo(a)pyrene.

The OWTS is designed to treat EPH and TSS, and the treatment process is expected to reduce concentrations of total metals (*e.g.,* T-Mn) and organic contaminants (*e.g.*, benzo(a)pyrene) bound to particulates that will settle into the treatment sludge. Model predictions for the above-listed POCs are below WQGs in the OUT-10 effluent. Therefore, after implementation of OWTS treatment, the modelled concentrations of these POCs in effluent are not expected to have adverse residual effects on the receiving environment.

5.4.3 TSS

The MDO for TSS in OWTS treated effluent is 25 mg/L (Section 4.2.1.3). It is expected that there will be periods (*i.e.,* during dry conditions) when the OWTS treated effluent is the only source of water being discharged at OUT-10 (Section 5.1). Therefore, the residual effects associated with the modelled effluent discharge of 25 mg/L TSS (expected and extreme case scenarios) from OUT-10 to the marine receiving environment are presented below.

5.4.3.1 Ecological Context

The Project foreshore serves as habitat for a wide variety of marine biota, including intertidal communities, fish, and marine mammals (Section 3.11), indicating that the marine receiving environment for effluent discharge has a **high ecological context**.

This rating reflects the possible presence of sensitive habitats or species with high ecological value in the receiving environment as the project continues to improve legacy site conditions. Pre-construction baseline biophysical surveys showed the intertidal and subtidal zones within the Project area consisted of marginal quality habitat (Keystone, 2024a). The intertidal zone was characterized by hard substrate and a band of rockweed occupying large boulders that are infrequently disturbed by wave actions. Below the rockweed band, sparse patches of sea lettuce and laminarian kelp were observed. The subtidal zone was characterized mostly by soft sediment comprised of wood debris, sand, and silt; where the lack of a hard substrate limits the diversity and abundance of sessile invertebrates. Dive surveys determined that although the Project area supports herring spawning, suitable spawning habitat has been limited in spatial extent, with observed spawn generally confined to a narrow band of rocky substrate supporting rockweed and kelp in the intertidal and shallow subtidal zones near the southwest corner of the Project area boundary since removal of legacy creosote piles (Keystone, 2024a; Keystone, 2025a). Proposed habitat offsetting as outlined in the *Fisheries Act* authorization for the Project includes placement of a combination of hard and soft substrates to improve the overall ecological health in the Project area. The habitat offsetting is planned for marine areas outside of the 100 m IDZ for OUT-10 that is proposed in Section 4.4.5.

5.4.3.2 Magnitude

B.C. has established WQGs for TSS that are protective of marine life from adverse effects, such as inhibiting photosynthesis due to decreased light penetration, physically smothering benthic communities, interfering with food intake, and clogging or abrasion of gills. The B.C. short-term marine WQG for TSS in clear water is an increase from background of 25 mg/L for a duration of 24 hours. The B.C. long-term WQG for TSS is an increase of

5 mg/L above background for a duration of 30 days. For the purpose of this assessment, the background TSS in the receiving environment is 3 mg/L based on the median value measured at 0.5 m below the surface in marine CPA stations from May 2020 to May 2025 (Table 3-30, Section 3.6). This indicates that OUT-10 effluent with 25 mg/L TSS will always be below the short-term WQG of 28 mg/L (25 mg/L plus 3 mg/L background), and that some dilution in the receiving environment will be required to bring effluent with 25 mg/L TSS to below the long-term WQG (8 mg/L; 5 mg/L plus 3 mg/L background) for the protection of MWAL.

Mixing zone modelling (Section 4.4) was conducted to derive concentrations of POCs at various distances from the point of discharge at OUT-10. Results of the mixing zone modelling show rapid dilution of TSS as effluent mixes with receiving environment waters. The axis of maximum concentration of the effluent plume is predicted to have TSS concentrations below the long-term WQG within 60 m of the outfall under all modelled wind conditions (low, medium and high wind) for the expected and extreme case scenarios (Figure 5-2). Since the modelled TSS concentration is less than the long-term WQG at the edge of the IDZ, the magnitude of TSS increases due to OUT-10 effluent discharge is characterized as low for both model scenarios.

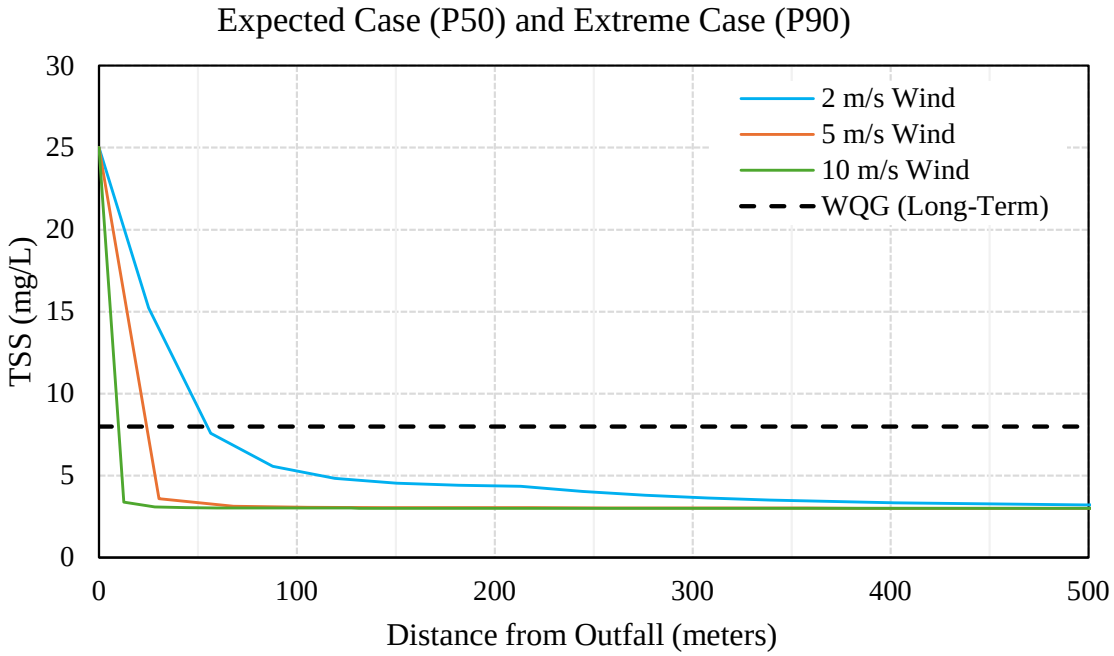

Figure 5-2: Total suspended solids (TSS) effluent plume predictions for both expected case and extreme case model scenarios. Modelled TSS concentration in effluent discharged from OUT-10 (25 mg/L) reflects 100% treated OWTS effluent under dry conditions.

5.4.3.3 Spatial Extent

All modelled TSS concentrations in the receiving environment are less than the short-term WQG. Modelled TSS concentrations are greater than the long-term WQG only within the IDZ (100 m from the outfall; Figure 5-2), for the expected and extreme case scenarios. Since TSS concentration is modelled to be below the long-term WQG at the edge of the IDZ, the spatial extent is characterized as **local**.

5.4.3.4 Duration

As discussed in Section 4.2.2.1, the OWTS operates in 12-hour batch cycles; therefore, the duration of increased TSS levels in the receiving environment associated with OUT-10 effluent discharge is characterized as **short-term**.

5.4.3.5 Frequency

As discussed in Section 5.1, the OWTS will be operated infrequently during dry conditions (approximately once or twice per month) for maintenance or to empty the Oily Water Storage Tank in advance of a rainfall event. Therefore, the frequency of increased TSS levels in the receiving environment associated with OUT-10 effluent discharge is characterized as **sporadic.**

5.4.3.6 Reversibility

After the discharge of OUT-10 effluent is stopped, it is expected that TSS concentration in the receiving environment will decrease to background levels within 1 to 2 days (Section 4.4); therefore, the reversibility is characterized as **reversible short-term**.

5.4.3.7 Summary of Potential Residual Effects

The residual effects characterizations from TSS in effluent discharged at OUT-10 are summarized in Table 5-1. Given the low magnitude, local spatial extent, short-term duration, sporadic frequency, and short-term reversibility of the residual effects characterization, **it is unlikely that the modelled TSS in OUT-10 effluent will have an adverse effect on aquatic life in the receiving environment.** The confidence in this assessment is considered high given: 1) it is expected that the OWTS will be operated as designed and will produce effluent with ≤25 mg/L TSS; 2) TSS predictions are lower than the long-term WQG at the edge of IDZ under all wind conditions (low, medium and high wind) modelled for both expected and extreme case scenarios; and, 3) the long-term WQG is based on a 30-day duration, whereas the dry condition model scenario is based on infrequent operation of the OWTS (*i.e.*, approximately once or twice per month).

Therefore, it is unlikely that the discharge from the OWTS alone during dry conditions would be sustained long enough to exceed the long-term WQG over a 30-day period.

Table 5-1:
Effect Assessment Ratings for Total Suspended Solids (TSS)

Category	Expected/Extreme Case
Ecological context	High
Magnitude	Low
Spatial extent	Local
Duration	Short-term
Frequency	Sporadic
Reversibility	Reversible short-term

5.4.4 T-Cu and T-Zn

Marine WQGs for total metals have been established in B.C. to protect the most sensitive species and life stages against acute toxicity (*e.g.*, mortality) over a defined short-term exposure period (*e.g.,* 96 hours), and against chronic toxicity (*e.g.*, growth inhibition) from long-term exposures. Of the total metals modelled, T-Cu and T-Zn have model predictions greater than their respective WQGs in effluent discharged from OUT-10 (Table 5-2). Specifically:

- The modelled T-Cu concentration in the OUT-10 effluent is greater than the long-term WQG in the expected case and greater than the long-term and short-term WQGs in the extreme case. The modelled T-Cu concentration in the OUT-10 effluent is primarily associated with the particulate fraction (68% for both expected case and extreme case). The source of particulate-bound Cu at OUT-10 is the 25 mg/L of TSS modelled for OWTS treated effluent. It is expected that there will be periods during dry conditions when the OWTS treated effluent is the only source being discharged at OUT-10 (Section 5.1).
- Modelled concentrations of T-Zn are greater than the long-term WQG at OUT-10 for the extreme case only. Similar to T-Cu, the modelled T-Zn is primarily associated with the particulate fraction (71% for extreme case).

Assessment of residual effects associated with the modelled discharge of T-Cu and T-Zn from OUT-10 to the marine receiving environment are presented below.

Table 5-2:
Modelled Copper and Zinc Concentrations in Site Effluent Discharged at OUT-10 during Dry Conditions

Modelled Parameter	Effluent Concentration (mg/L)		Particulate Fraction (%)		B.C. WQG (mg/L)	
	Expected Case	Extreme Case	Expected Case	Extreme Case	Long-Term	Short-Term
T-Cu	***0.0021***	***0.0034***	68	68	0.002	0.003
D-Cu	0.00068	0.0011			-	-
T-Zn	0.0074	***0.014***	85	71	0.01	0.055
D-Zn	0.0011	0.0040			-	-

Notes:
Values ***underlined in bold italics*** are above the B.C. long-term WQG for the protection of marine water aquatic life. Values shaded are above the B.C. short-term WQG for the protection of marine water aquatic life.

5.4.4.1 Ecological Context

The Project foreshore serves as habitat for a wide variety of marine biota, including intertidal communities, fish, and marine mammals (Section 3.11), indicating that the marine receiving environment for effluent discharge has a **high ecological context**.

This rating reflects the possible presence of sensitive habitats or species with high ecological value in the receiving environment as the project continues to improve legacy site conditions. Pre-construction baseline biophysical surveys showed the intertidal and subtidal zones within the Project area consisted of marginal quality habitat (Keystone, 2024a). The intertidal zone was characterized by hard substrate and a band of rockweed occupying large boulders that are infrequently disturbed by wave actions. Below the rockweed band, sparse patches of sea lettuce and laminarian kelp were observed. The subtidal zone was characterized mostly by soft sediment comprised of wood debris, sand, and silt; where the lack of a hard substrate limits the diversity and abundance of sessile invertebrates. Dive surveys determined that although the Project area supports herring spawning, suitable spawning habitat has been limited in spatial extent, with observed spawn generally confined to a narrow band of rocky substrate supporting rockweed and kelp in the intertidal and shallow subtidal zones near the southwest corner of the CPA since removal of legacy creosote piles (Keystone, 2024a; Keystone, 2025a). Proposed habitat offsetting as outlined in the *Fisheries Act* authorization for the Project includes placement of a combination of hard and soft substrates to improve the overall ecological health in the Project area. The habitat offsetting is planned for marine areas outside of the 100 m IDZ for OUT-10 that is proposed in Section 4.4.5.

5.4.4.2 Magnitude

Modelled T-Cu concentrations at OUT-10 are up to 1.7 times the long-term WQG (0.002 mg/L) based on the dry condition extreme case scenario (Table 5-2). The maximum T-Cu concentration modelled at OUT-10 is also above the short-term WQG (0.003 mg/L) for the dry condition extreme case scenario. For context, T-Cu concentrations in marine water samples collected within the Project area ranged from <0.0005 to 0.00532 mg/L (0.5 m below surface; Table 3-30) and at reference stations the T-Cu concentration ranged from <0.0005 to 0.00442 mg/L (0.5 m below surface, Section 3.9.3 and Appendix 3.9-1). The modelled T-Cu concentrations at OUT-10 are within the range observed under existing conditions. Additionally, the modelled T-Cu concentration in OUT-10 effluent is mostly associated with the particulate fraction, which has relevance to the magnitude rating since particulate-bound Cu is less bioavailable than the D-Cu fraction. Comparison of the readily bioavailable D-Cu fraction to the T-Cu WQGs shows that the D-Cu fraction is lower than the long-term WQG in undiluted OUT-10 effluent (Table 5-2).

Results of the mixing zone modelling for T-Cu are shown in Figure 5-3 for the dry condition. The OUT-10 effluent plume is modelled to have T-Cu concentrations below the short-term WQG at the point of discharge (expected case) and within 25 m (extreme case) of the outfall; and T-Cu predictions are below the long-term WQG near the point of discharge (expected case) and within 40 m (extreme case) of OUT-10. Since modelled T-Cu concentrations at OUT-10 are less than the long-term WQG at the edge of the IDZ, the magnitude of T-Cu increases due to effluent discharge is characterized as **low** for both model scenarios.

Results of the mixing zone modelling for T-Zn are shown in Figure 5-4 for the dry condition. Modelled concentrations of T-Zn in the OUT-10 effluent plume meet the long-term WQG at the point of discharge (expected case) and within 25 m from the outfall (extreme case). As with T-Cu, the magnitude rating is characterized as **low** for T-Zn since the modelled concentrations of these total metals at OUT-10 are less than their long-term WQGs at the edge of the IDZ.

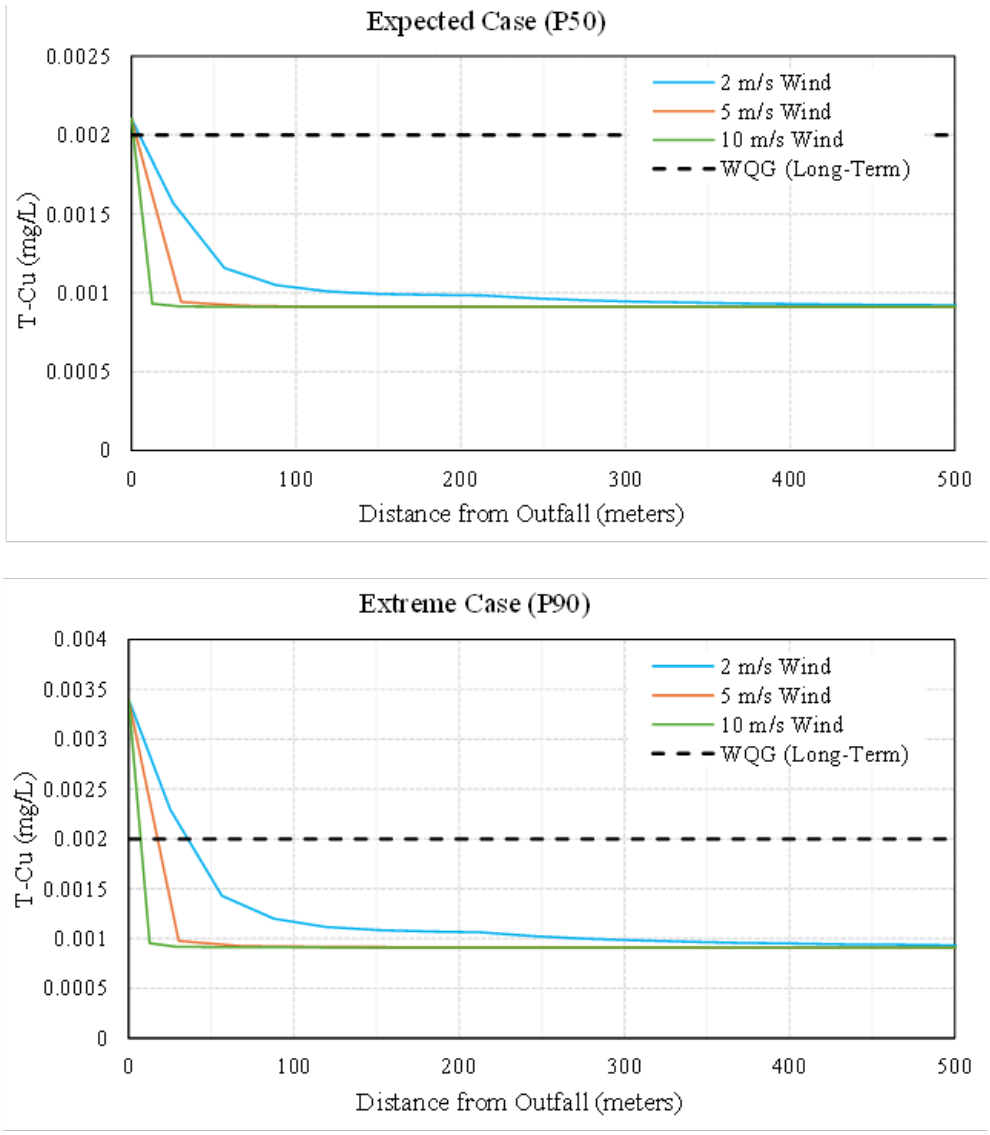

Figure 5-3: Modelled total copper (T-Cu) effluent plume predictions for the expected case (upper plot) and extreme case (lower plot) model scenarios. Modelled concentrations in effluent discharged from OUT-10 reflect 100% treated OWTS effluent under dry conditions.

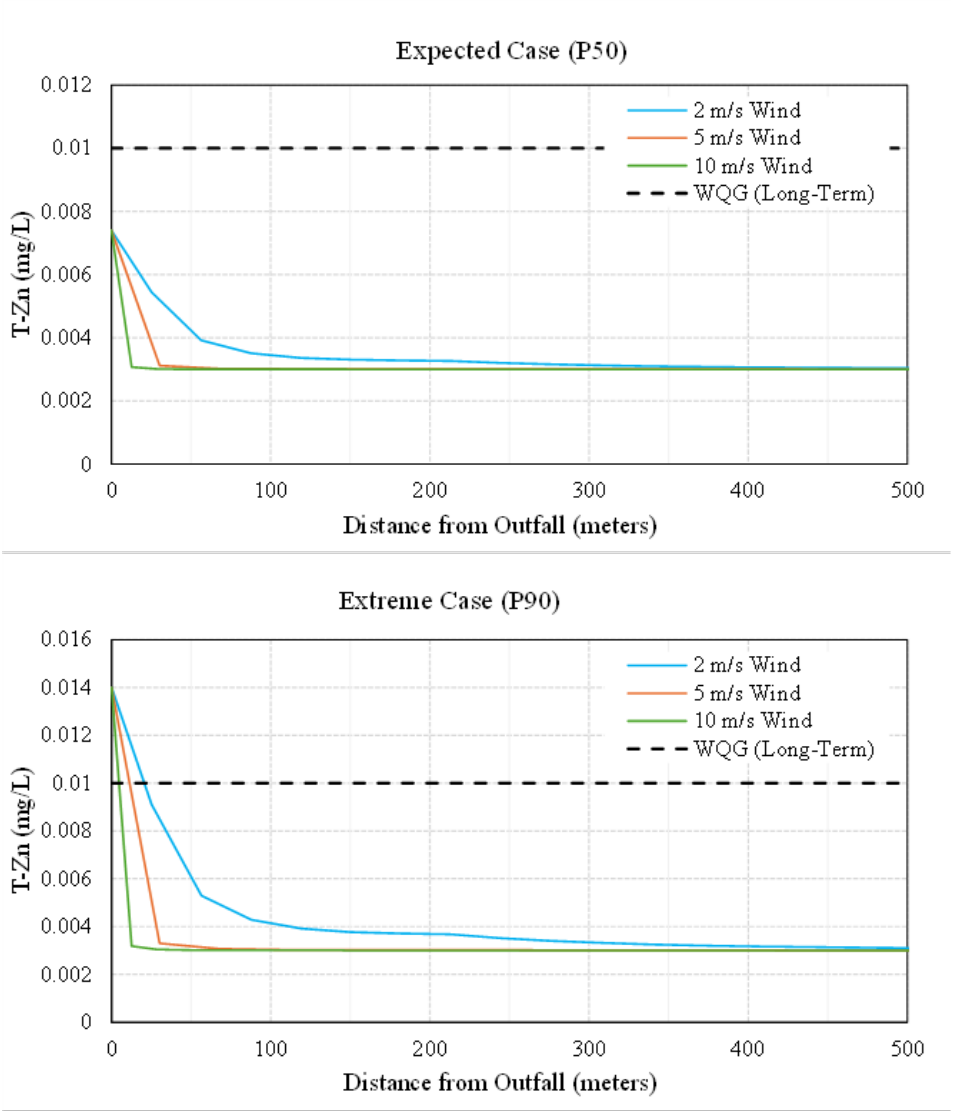

Figure 5-4: Modelled total zinc (T-Zn) effluent plume predictions for the expected case (upper plot) and extreme case (lower plot) model scenarios. Modelled concentrations in effluent discharged from OUT-10 reflect 100% treated OWTS effluent under dry conditions.

5.4.4.3 Spatial Extent

Under dry conditions, all modelled total metal concentrations in OUT-10 effluent are less than the short-term WQG except for T-Cu (extreme case only). Mixing of effluent with marine water is expected to reduce total metal concentrations to below the short-term and long-term WQGs at the edge of the IDZ from OUT-10 under all wind conditions modelled for the expected and extreme case models; therefore, the spatial extent is characterized as **local**.

5.4.4.4 Duration

As discussed in Section 4.2.2.1, the OWTS operates in 12-hour batch cycles; therefore, the duration of increased total metal concentrations in the receiving environment associated with OUT-10 effluent discharge is characterized as **short-term**.

5.4.4.5 Frequency

As discussed in Section 5.1, the OWTS will be operated infrequently during dry conditions (approximately once or twice per month) for maintenance or to empty the Oily Water Storage Tank in advance of a rainfall event. Therefore, the frequency of increased total metal concentrations in the receiving environment associated with OUT-10 effluent discharge is characterized as **sporadic.**

5.4.4.6 Reversibility

After the discharge of OUT-10 effluent is stopped, it is expected that total metal concentrations in the receiving environment will decrease to below the long-term WQGs or return to background conditions; therefore, the reversibility is characterized as **reversible short-term**.

5.4.4.7 Summary of Potential Residual Effects

The residual effects characterizations from modelled T-Cu and T-Zn in effluent discharged at OUT-10 are summarized in Table 5-3 and Table 5-4, respectively for dry conditions. Given the low magnitude, local spatial extent, short-term duration, sporadic frequency, and short-term reversibility of the residual effects characterization, **it is unlikely that the modelled total metal concentrations in OUT-10 effluent will have an adverse effect on aquatic life in the receiving environment.** The confidence in this assessment is considered high since the modelled concentrations are lower than their respective long-term WQGs at the edge of IDZ from OUT-10 under all wind conditions (low, medium and high wind) for both expected and extreme case scenarios. A high confidence rating is further supported by the characteristics of metals in the modelled effluent, which are predominantly in the particulate phase. Metals bound to particulates generally exhibit low bioavailability. Dissolved metal concentrations are more representative of the bioavailable fraction of total metals, and the modelled dissolved metal concentrations in the effluent are below long-term WQGs.

Table 5-3:
Effect Assessment Ratings for Total Copper (T-Cu) Modelled at OUT-10

Category	OUT-10	
	Expected Case	**Extreme Case**
Ecological context	High	High
Magnitude	Low	Low
Spatial extent	Local	Local
Duration	Short-term	Short-term
Frequency	Sporadic	Sporadic
Reversibility	Reversible short-term	Reversible short-term

Table 5-4:
Effect Assessment Ratings for Total Zinc (T-Zn) Modelled at OUT-10

Category	Expected Case	Extreme Case
Ecological context	High	High
Magnitude	Low	Low
Spatial extent	Not applicable[1]	Local
Duration	Not applicable[1]	Short-term
Frequency	Not applicable[1]	Sporadic
Reversibility	Not applicable[1]	Reversible short-term

Note:
[1] Not applicable indicates modelled concentrations in effluent are below long-term water quality guidelines, hence no rating is assigned.

5.4.5 EPH

The MDO for EPH in OWTS treated effluent is 15 mg/L (Section 4.2.1.3). It is expected that there will be periods during dry conditions when the OWTS treated effluent is the only source being discharged at OUT-10 (Section 5.1). Therefore, the residual effects associated with the discharge of modelled effluent with 15 mg/L EPH (expected and extreme cases) from OUT-10 to the marine receiving environment are assessed below.

5.4.5.1 Ecological Context

The Project foreshore serves as habitat for a wide variety of marine biota, including intertidal communities, fish, and marine mammals (Section 3.11), indicating that the marine receiving environment for effluent discharge has a **high ecological context**.

This rating reflects the possible presence of sensitive habitats or species with high ecological value in the receiving environment as the project continues to improve legacy

site conditions. Pre-construction baseline biophysical surveys showed the intertidal and subtidal zones within the Project area consisted of marginal quality habitat (Keystone, 2024a). The intertidal zone was characterized by hard substrate and a band of rockweed occupying large boulders that are infrequently disturbed by wave actions. Below the rockweed band, sparse patches of sea lettuce and laminarian kelp were observed. The subtidal zone was characterized mostly by soft sediment comprised of wood debris, sand, and silt; where the lack of a hard substrate limits the diversity and abundance of sessile invertebrates. Dive surveys determined that although the Project area supports herring spawning, suitable spawning habitat has been limited in spatial extent, with observed spawn generally confined to a narrow band of rocky substrate supporting rockweed and kelp in the intertidal and shallow subtidal zones near the southwest corner of the CPA since removal of legacy creosote piles (Keystone, 2024a; Keystone, 2025a). Proposed habitat offsetting as outlined in the *Fisheries Act* authorization for the Project includes placement of a combination of hard and soft substrates to improve the overall ecological health in the Project area. The habitat offsetting is planned for marine areas outside of the 100 m IDZ for OUT-10 that is proposed in Section 4.4.5.

5.4.5.2 Magnitude

This effects assessment evaluates effluent discharge from an LNG facility that is operated as designed, with effective mitigation measures and management plans implemented. The potential effects of incidents (*e.g.*, oil spills) on the receiving environment are not evaluated. Under normal operating conditions, stormwater that is potentially contaminated with EPH will be collected in curbed areas and conveyed to the OWTS for treatment. In the conveyance and treatment process, some degree of weathering (*e.g.,* evaporation, photo-oxidation, adsorption/settling) of EPH may occur prior to being discharged at OUT-10.

There are no B.C. or federal (CCME/ECCC) numeric WQGs established for EPH for the protection of aquatic life. While there are no Canadian WQGs for EPH, the Washington State Department of Ecology developed effects-based concentrations for weathered DRO that are considered protective of aquatic life in the marine and freshwater environment (Hobbs, Eickhoff, & Lee, 2020). Oil products are a mixture of organic compounds that can be chemically extracted from environmental samples (*e.g.*, water, soil, sediment). A detailed explanation of parameters that are used to measure oil in water is provided in Section 4.1.2. Commonly used parameter names include EPH, TPH, F2-F4 and DRO. The oil concentrations values reported by Hobbs, Eickhoff, & Lee (2020) are expressed as the DRO parameter, and is assumed to be directly comparable to results expressed using the EPH parameter defined in Section 4.1.2.

It is noted that Hobbs, Eickhoff, & Lee (2020) used contaminated groundwater from a well in the vicinity of underground diesel fuel tanks and waste oil tanks to prepare test solutions. Whereas lubricating, hydraulic and dielectric oils are expected to constitute the EPH in OWTS effluent. Although the oil sources are different, the results for weathered DRO are used to establish a reference value for evaluating EPH discharged from OUT-10.

The test organisms used in the marine studies conducted by Hobbs, Eickhoff, & Lee (2020). were topsmelt (Atherinops affinis) and sea urchin (Strongylocentrotus purpuratus), which are relevant to the Howe Sound receiving environment. The study showed no measurable chronic effects to the sea urchin from exposure to weathered DRO at the maximum concentration tested (2.71 mg/L). The study determined a no-observable effects concentration (NOEC) of 2.12 mg/L for the growth of topsmelt. In the absence of Canadian WQGs for EPH, this NOEC of 2.12 mg/L is used to characterize the magnitude of modelled changes to EPH concentration from OUT-10 effluent discharge.

Results of the mixing zone modelling for the dry condition show rapid dilution of EPH as OUT-10 effluent mixes with receiving environment waters. Under moderate wind (5 m/s) and high wind (10 m/s) conditions, modelled EPH concentrations decrease to less than the NOEC within 30 m from OUT-10 (Figure 5-5). Under low wind conditions (2 m/s), the modelled EPH concentration decreases from 15 mg/L in the OUT-10 effluent to 3 mg/L at approximately 56 m from the outfall, and to the NOEC (2.12 mg/L; Hobbs, Eickhoff, & Lee, 2020) at approximately 80 m from the outfall. Based on the above, the magnitude of EPH concentration increases due to OUT-10 effluent discharge is characterized as low for both model scenarios.

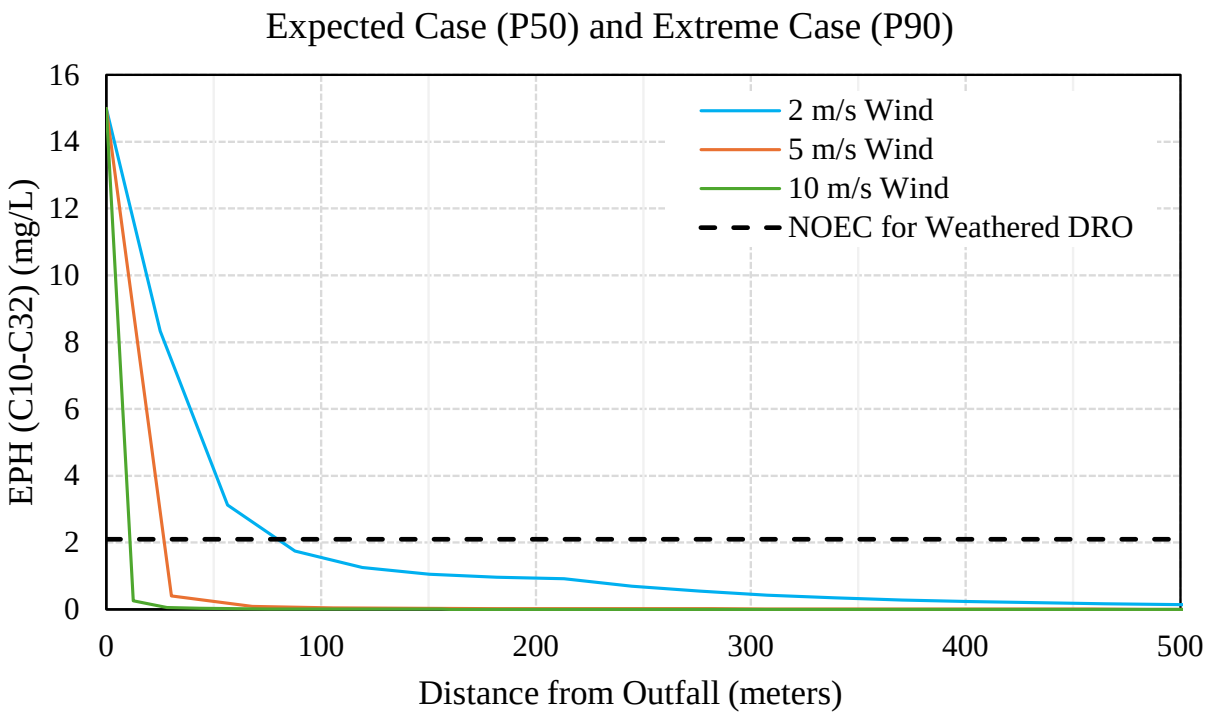

Figure 5-5: Extractable petroleum hydrocarbons (EPH) effluent plume predictions for both expected case and extreme case model scenarios. Modelled EPH concentration in effluent discharged from OUT-10 (15 mg/L) reflects 100% treated OWTS effluent under dry conditions.

5.4.5.3 Spatial Extent

Mixing of effluent with marine water is expected to reduce EPH concentrations to below the no-effects threshold (2.12 mg/L; Hobbs, Eickhoff, & Lee, 2020) at the edge of the IDZ from OUT-10 under all wind conditions modelled for the expected and extreme case models; therefore, the spatial extent is characterized as **local**.

5.4.5.4 Duration

As discussed in Section 4.2.2.1, the OWTS operates in 12-hour batch cycles; therefore, the duration of increased EPH concentrations in the receiving environment associated with OUT-10 effluent discharge is characterized as **short-term**.

5.4.5.5 Frequency

As discussed in Section 5.1, the OWTS will be operated infrequently (approximately once or twice per month) during dry conditions, for maintenance or to empty the Oily Water Storage Tank in advance of a rainfall event. Therefore, the frequency of increased EPH concentrations in the receiving environment associated with OUT-10 effluent discharge is characterized as **sporadic.**

5.4.5.6 Reversibility

After the discharge of OUT-10 effluent is stopped, it is expected that EPH concentration in the receiving environment will decrease to levels below the no-effects threshold (2.12 mg/L; Hobbs, Eickhoff, & Lee, 2020); therefore, the reversibility is characterized as **reversible short-term**.

5.4.5.7 Summary of Potential Residual Effects

The characterizations of changes to EPH concentration in the receiving environment from discharge of effluent at OUT-10 are summarized in Table 5-5. Given the characterization as low magnitude, local spatial extent, short-term duration, sporadic frequency, and short-term reversibility, **it is unlikely that the modelled EPH in OUT-10 effluent will have an adverse effect on aquatic life in the receiving environment.**

Table 5-5:
Effect Assessment Ratings for Extractable Petroleum Hydrocarbons (EPH)

Category	Expected/Extreme Case
Ecological context	High
Magnitude	Low
Spatial extent	Local
Duration	Short-term
Frequency	Sporadic
Reversibility	Reversible short-term

The confidence in this assessment is moderate. Key uncertainties pertain to the composition and extent of weathering of EPH in OUT-10 effluent, both of which have bearing on aquatic toxicity. Monitoring of water quality will be implemented (according to the program described in Section 6.2) to determine the concentration of EPH in OUT-10 effluent and the receiving environment. Acute and chronic toxicity testing will be conducted to assess the potential for toxic effects of effluent discharge on aquatic life.

5.4.6 Summary

Contact water from the Project site is expected to be discharged during stormwater events, and occasionally (approximately once or twice per month) when the Oily Water Storage Tank is emptied during dry conditions. Effluent quality at OUT-10 was modelled for two source term scenarios (expected case and extreme case). Modelled concentrations under dry conditions, when the OUT-10 discharge consists solely of treated effluent from the OWTS, were higher than those predicted for stormwater conditions. As a conservative approach, modelled concentrations of POCs in the OUT-10 discharge under dry conditions

(TSS, T-Cu, T-Zn, and EPH) were assessed for potential residual effects on aquatic life in the marine environment.

A mixing model was used to estimate concentrations of POCs in the receiving environment under low, moderate, and high wind speeds. The modelled concentrations in the receiving environment were used to characterize the magnitude and spatial extent of changes to water quality from the discharge of treated effluent. The ecological context of the receiving environment, as well as the duration, frequency, and reversibility of changes to water quality from the discharge of effluent, were also characterized. The ratings were consistent across the four POCs assessed (Table 5-6). The marine receiving environment of Howe Sound is rated high ecological context, with marginal quality habitat in the intertidal and subtidal zones within the Project area. Given the low magnitude, local spatial extent, short-term duration, sporadic frequency, and reversible short-term ratings, it was concluded that the modelled discharge of OUT-10 effluent is unlikely to cause adverse effects to aquatic life in the receiving environment.

Table 5-6:
Summary of Effect Assessment Ratings for Parameters of Concern

Category	TSS	T-Cu and T-Zn	EPH
Ecological context	High	High	High
Magnitude	Low	Low	Low
Spatial extent	Local	Local	Local
Duration	Short-term	Short-term	Short-term
Frequency	Sporadic	Sporadic	Sporadic
Reversibility	Reversible short-term	Reversible short-term	Reversible short-term

The confidence in the ratings was determined to be high for TSS, T-Cu, and T-Zn, and moderate for EPH. The lower confidence in the EPH rating reflects greater uncertainty in the composition and extent of weathering of EPH in the effluent compared to TSS and total metals.

5.5 Cumulative Effects

This section discusses the potential for receiving environment water quality to be affected by past, present, and future effluents discharged within the Project area boundaries, thereby contributing to cumulative effects on aquatic life from changes to water quality. The current and planned effluent discharges within the Project area boundaries are summarized in Table 5-7. The foreseeable effluent discharges during Project operations will originate from the Landfill Leachate Treatment Plant, the Sewage Treatment Plant, and the OWTS. Construction related discharges from the East and West Sedimentation Ponds to Howe

Sound, and from the Fortis-led Eagle Mountain Woodfibre Gas Pipeline Project to East Creek, are planned to cease when construction is completed. Cumulative effects from pre-construction and construction effluent discharges in the Howe Sound receiving environment, within Project boundaries, are considered to be accounted for in the monitoring results presented in Section 3. The residual effects assessment (Section 5.4) indicates that the modelled OWTS discharge from OUT-10 is unlikely to cause adverse effects to aquatic life in the receiving environment.

During operations, effluent from OUT-10 will discharge from the shoreline to the Howe Sound surface waters, whereas the Sewage Treatment Plant and the Landfill Leachate Treatment Plant will discharge to deeper waters underlying the surface layer (Table 5-7). As discussed in Section 3.10, mixing between the surface and deeper waters is limited by water column stratification. The mixing model (Section 4.4) indicates that the OUT-10 effluent will form a buoyant plume that mixes with the surface layer of Howe Sound. Due to water column stratification and the spatial separation of the discharge locations (Table 5-7), discharges of treated domestic wastewater and treated leachate effluent to the deep water are unlikely to mix with the surface discharge from OUT-10; therefore, cumulative effects of these effluents are unlikely and not assessed in this TAR.

Table 5-7:
Summary of Effluent Discharges Within Project Area Boundaries

Effluent Source	Effluent Permit Number	Discharge Period	Description of Discharge
Landfill Leachate Treatment Plant	1239	P, C, O	Underwater discharge of treated landfill leachate to Howe Sound at approximately 22 m depth and approximately 220 m southwest of OUT-10.
Sewage Treatment Plant	2334	P, O	Underwater discharge to Howe Sound at approximately 25 m depth and approximately 770 m southwest of OUT-10. Treated domestic wastewater has not been discharged during most of construction because the wastewater was collected and disposed off-site at a licenced domestic wastewater treatment facility. Discharge is forecast to resume just before or during early operations.
West Sedimentation Pond	111578	C	Shoreline discharge of non-contaminated construction contact water to Howe Sound from SP-W-OUT (OUT-04), located approximately 530 m southwest of OUT-10. Sedimentation pond discharge is forecast to cease when the transition from the construction to operations water management system is completed (Section 4.1.10.2).
East Sedimentation Pond	111578	C	Shoreline discharge of non-contaminated construction contact water to Howe Sound from SP-E-OUT (OUT-10). This is the same outfall as OUT-10. Sedimentation pond discharge is forecast to cease when the transition from the construction to operations water management system is completed (Section 4.1.10.2).
Eagle Mountain – Woodfibre Gas Pipeline Project (FortisBC)	110163	C	The Eagle Mountain Woodfibre Gas Pipeline Project is operated by FortisBC. The Woodfibre side of the tunnel construction effluent is discharged to East Creek, which in turn discharges to the Howe Sound shoreline from OUT-12, approximately 70 m northeast of OUT-10. It is understood that effluent discharge is planned to cease when construction is completed.
OWTS Effluent and Stormwater Runoff (OUT-10)	WDA Permit application in progress	O	Treated OWTS effluent and non-contaminated stormwater runoff discharged to Howe Sound from OUT-10. Comingled OWTS effluent and stormwater runoff discharge is forecast to commence when the transition from the construction to operations water management system is completed (Section 4.1.10.2).

Discharge period notes: P = pre-construction, C = construction, O = operations

6. Proposed Discharge Limits and Monitoring Plan

6 Proposed Discharge Limits and Monitoring Plan

This section outlines the proposed discharge limits and monitoring plan to support WLNG's request for authorization to discharge treated effluent from the OWTS to the adjacent waters of Howe Sound.

6.1 Discharge Limits

Proposed discharge limits are intended to establish maximum allowable discharge concentrations for parameters directly influenced by Project operations (*i.e.*, TSS and EPH). The effluent model (Section 4.3) predicts that TSS, T-Cu, T-Zn and pH concentrations discharged at OUT-10 may exceed WQGs for the protection of MWAL, and EPH concentrations may exceed the NOEC value derived for the growth of topsmelt. However, the mixing model (Section 4.4) predicts effluent will be rapidly diluted in Howe Sound within the IDZ. Based on these results, the effects assessment (Section 5) concluded that the predicted concentrations of TSS, T-Cu, T-Zn, pH, and EPH are unlikely to result in adverse effects to the receiving environment, even under the dry condition extreme case model scenario.

The highest predicted T-Cu and T-Zn concentrations are attributed to the particulate-bound fractions of the metals, which are considered less bioavailable than their dissolved forms. The dissolved fraction concentrations of these metals (*i.e.*, D-Cu and D-Zn) are predicted to be below the corresponding T-Cu and T-Zn WQGs for the protection of MWAL. The effects assessment concluded that the predicted concentrations of T-Cu and T-Zn in OUT-10 effluent are unlikely to result in adverse effects to the receiving environment. These parameters do not originate from the LNG manufacturing process and instead are associated with TSS that may accumulate in the LNG Processing Area from windblown sources or from vehicle traffic. Additionally, the maximum predicted concentrations of T-Cu and T-Zn in OUT-10 effluent are within the range of observed conditions for Howe Sound waters, with maximum observed values of 0.00974 mg/L for T-Cu, and 0.102 mg/L for T-Zn (Section 3.9.3). Based on the preceding considerations, discharge limits for T-Cu and T-Zn are not proposed.

The effluent model predicts that pH in effluent discharged from OUT-10 will exceed the WQG for the protection of MWAL. However, the effects assessment concluded that the lowest modelled pH for contact and non-contact water reflects natural background conditions in creek and non-contact water within the Project area and is therefore not

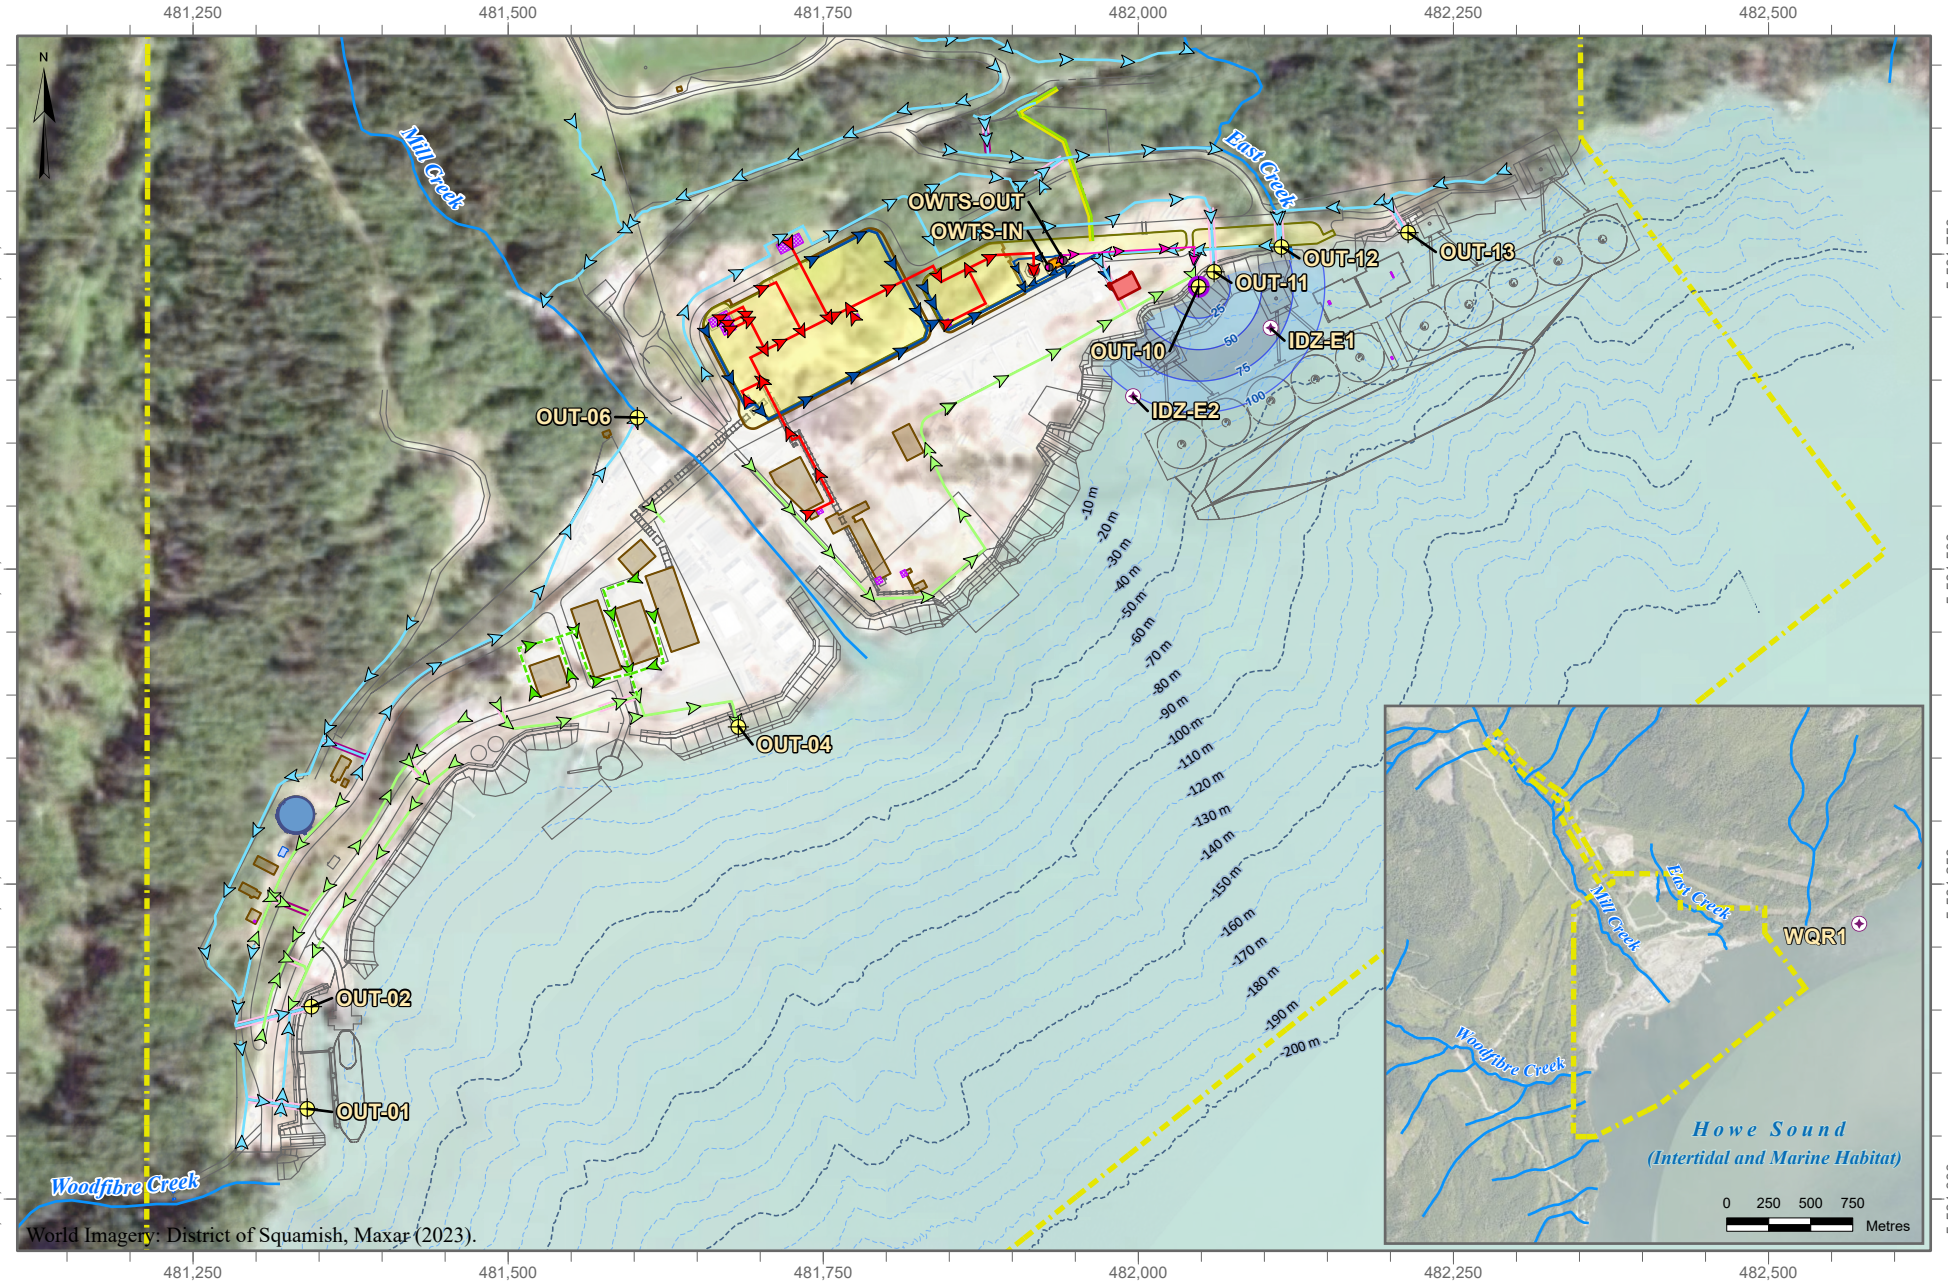
expected to result in adverse residual effects on the receiving environment. Therefore, a discharge limit for pH is not proposed.

In consideration of the predicted effluent quality for OUT-10, the results of the effects assessment, and the observed water quality of Howe Sound, it is proposed that the WDA discharge limits at OUT-10 be set equal to the dry condition predicted values for TSS and EPH that are shown in Table 6-1 and described in Section 4.3.3.4.

Table 6-1:
Proposed Discharge Limits for OUT-10 Discharge to Howe Sound

Parameter	Discharge Limit
TSS	25 mg/L
EPH (C10-C32)	15 mg/L

6.2 Monitoring Plan



This section describes the proposed water quality monitoring program to support the requested WDA discharge limits described in Section 6.1. Contaminated or potentially contaminated contact water that has been assessed as suitable for on-site treatment will be directed to the OWTS (Section 4.1.5). Monitoring will be conducted to confirm the treatment performance of the OWTS and to confirm that the discharge quality meets WDA limits. The receiving environment near the OWTS discharge outfall location (OUT-10) will also be monitored.

The monitoring program encompasses three key components of the effluent management system:

1) the OWTS;
2) the outfalls; and
3) the receiving environment.

The monitoring plan for each is described below (Sections 6.2.1, 6.2.2, and 6.2.3, respectively), along with quality assurance and quality control (Section 6.2.4). TSS compliance at OUT-10 will be evaluated through a turbidity-TSS relationship, as discussed in Section 6.2.5. Proposed monitoring locations are presented in Figure 6-1.

All field water quality monitoring and sampling will be completed by trained personnel in accordance with the British Columbia Field Sampling Manual (Clark, 2013). Monitoring samples will be submitted for analytical testing to a laboratory qualified under the B.C. Environmental Data Quality Assurance Regulation, and following the procedures described the British Columbia Environmental Laboratory Manual (ENV, 2023).

TITLE: Proposed WDA Water Quality Monitoring and Compliance Locations

PROJECT #: A825-1

FIGURE: 6-1

6.2.1 OWTS Monitoring

The objectives of the OWTS monitoring program are to:

a) assess efficacy of the treatment process for the OWTS; and

b) monitor the water quality and volume of treated effluent from the OWTS being discharged to Howe Sound.

A sampling port for the influent to the OWTS (OWTS-IN) will be located on the influent pipe from the Oily Water Storage Tank. Treated effluent will be monitored on the treated effluent line from the OWTS, at station OWTS-OUT (Figure 6-1).

Monitoring locations, frequencies, and parameter groups to be analyzed are presented in Table 6-2. Detailed parameter lists for each parameter group are presented in Appendix 6.1-1. The routine monitoring plan encompasses daily to monthly sampling, depending on parameter group (Table 6-2). Field parameters and flows will be monitored daily, while the full suite of analytical parameters (*i.e.,* physical and general parameters, BTEX and VH, EPHs and PAHs, and total and dissolved metals) will be monitored monthly.

6.2.2 Outfall Monitoring

Monitoring will be conducted at the outfalls that route non-contact and non-contaminated stormwater runoff to the receiving environment. A total of eight stormwater runoff discharges are included in the outfall monitoring plan, including OUT-10, which also discharges treated effluent from the OWTS. The objectives of the outfall monitoring program are to:

a) assess compliance with the conditions of the WDA; and

b) monitor the water quality of stormwater runoff, including stormwater comingled with treated OWTS effluent at OUT-10, discharged to the receiving environment.

At outfalls OUT-01, OUT-06, OUT-11, OUT-12, OUT-13 (Figure 6-1), field parameters will be monitored monthly, while the complete analytical suite (*i.e.,* physical and general parameters, BTEX & VH, EPHs and PAHs, and total and dissolved metals) will be monitored on a quarterly basis during the first year of operations to confirm the effectiveness of the stormwater diversion measures. Following this verification period, monitoring at these outfalls will be discontinued.

Monitoring at OUT-02 and OUT-04 (Figure 6-1) will be conducted monthly for field parameters and quarterly for full analytical suite to verify water quality at outfalls that receive a significant amount of non-contaminated contact water from the Project site.

Table 6-2:
Monitoring Plan for the Oily Water Treatment System

Station Name	Sample Type	Description	Coordinates [1]		Flow Rate	Field Parameters	Physical Parameters	General Chemistry	VH & BTEX	EPHs & PAHs	Metals – Total & Dissolved
			Latitude	Longitude							
OWTS-IN	Influent	Influent to the OWTS from the Oily Water Storage Tank.	49.6680º	-123.2504º	D	D	M	M	M	M	M
OWTS-OUT	Effluent	Effluent from the OWTS.	49.6680º	-123.2503º	D	D	M	M	M	M	M

Notes:
[1] Coordinates are approximate and subject to revision based on final as-built conditions. All coordinates are in UTM Zone 10 U.
D = daily M = monthly
Sampling will only be conducted when the OWTS is operational and actively treating/discharging water.
Sampling of field and physical parameters at OWTS-OUT will be synchronized to produce paired field turbidity and laboratory TSS data, enabling development of a turbidity-TSS relationship (refer to Section 6.2.5).

At OUT-10 (Figure 6-1), field parameters will be monitored daily (when there is a rainfall event and/or a OWTS batch operation), while analytical parameters will be monitored monthly. In addition, quarterly acute toxicity testing will be conducted in effluent discharged at OUT-10.

A summary of the proposed sampling locations, sampling frequencies, and parameter groups for outfall water samples is presented in Table 6-3. A list of water quality parameters to be analyzed for each parameter group is provided in Appendix 6.1-1.

6.2.3 Receiving Environment Monitoring

The objectives of the receiving environment monitoring program are to:

a) assess compliance with the conditions of the WDA;

b) detect change and long-term trends in the receiving environment; and

c) identify any potential environmental effects associated with discharge from the Project site.

Receiving environment water quality will be evaluated considering reference station water quality conditions and applicable regulatory guidelines (*i.e.*, Federal and B.C. WQGs) and/or WDA discharge limits.

The marine receiving environment monitoring program has been designed to monitor water quality in the mixing zone immediately downstream of the OUT-10 discharge. The water column will be sampled at two IDZ monitoring stations (IDZ-E1 and IDZ-E2) located approximately 50 to 100 m from the OUT-10 contact water discharge outfall, and at a nearshore reference site located approximately 500 m northeast of the Project site (WQR1) (Figure 6-1). Field measurements and testing for the full suite of analytical parameters (*i.e.*, physical parameters, general parameters, BTEX & VH, EPHs & PAHs, total and dissolved metals) will be conducted monthly for the first year of operations, followed by quarterly sampling thereafter. In addition, chronic toxicity testing will be conducted quarterly.

A summary of the proposed sampling locations, sampling frequencies, and parameter groups for freshwater and marine water samples is presented in Table 6-4. A list of water quality parameters to be analyzed for each parameter group is provided in Appendix 6.1-1.

Table 6-3:
Monitoring Plan for Outfalls

Station Name	Sample Type	Description	Coordinates		Field Parameters	Physical Parameters	General Parameters	BTEX & VH	EPHs & PAHs	Metals[1]	Acute Toxicity[2]
			Latitude	Longitude							
Stormwater Runoff / Treated Effluent Discharge											
OUT-10	Effluent	Discharge of non-contaminated and treated contaminated/potentially contaminated contact water from the East side of Mill Creek to Howe Sound.	49.6678º	-123.2488º	D [4]	M	M	M	M	M	Q
Stormwater Runoff Discharges											
OUT-01 [3]	Freshwater	Discharge of predominantly non-contact water, with small inputs of non-contaminated contact water, from the West side of Mill Creek to Howe Sound.	49.6619º	-123.2585º	M	Q	Q	Q	Q	Q	-
OUT-02	Freshwater	Discharge of predominantly non-contact water, with small inputs of non-contaminated contact water, from the West side of Mill Creek to Howe Sound, and from periodic backflushing of the Fire Water Tank filtration system.	49.6626º	-123.2585º	M	Q	Q	Q	Q	Q	-
OUT-04	Freshwater	Discharge of non-contaminated contact water from the West side of Mill Creek to Howe Sound.	49.6646º	-123.2538º	M	Q	Q	Q	Q	Q	-
OUT-06 [3]	Freshwater	Discharge of predominantly non-contact water, with small inputs of non-contaminated contact water, from the West side of Mill Creek to Mill Creek.	49.6668º	-123.2549º	M	Q	Q	Q	Q	Q	-
OUT-11 [3]	Freshwater	Discharge of non-contact water and non-contaminated contact water from East side of Mill Creek to Howe Sound.	49.6679º	-123.2486º	M	Q	Q	Q	Q	Q	-
OUT-12 [3]	Freshwater	Discharge of East Creek (containing predominantly non-contact water, with small inputs of non-contaminated contact water) to Howe Sound.	49.6681º	-123.2479º	M	Q	Q	Q	Q	Q	-
OUT-13 [3]	Freshwater	Discharge of predominantly non-contact water, with small inputs of non-contaminated contact water, from the East side of Mill Creek to Howe Sound.	49.6682º	-123.2465º	M	Q	Q	Q	Q	Q	-

All coordinates are in UTM zone 10 U. Coordinates for the outfall are at the point of discharge; actual monitoring locations will be finalized when the facilities are constructed.
D = daily
M = monthly
Q = quarterly
Sampling will be conducted only when discharge flow occurs during the specified monitoring period.
Sampling of field and physical parameters at OUT-10 will be synchronized to produce paired field turbidity and laboratory TSS data, enabling development of a turbidity-TSS relationship (refer to Section 6.2.5).
[1] Water quality samples will be tested for dissolved and total metals
[2] Acute Toxicity testing will be conducted with 100% effluent using a fish species and an invertebrate species.
[3] After the first year of monitoring, monitoring requirements at select outfalls (OUT-01, OUT-06, OUT-11, OUT-12 and OUT-13) will be discontinued.
[4] Field measurements will be taken daily at OUT-10 when there is a rainfall event and/or a OWTS batch operation.

Table 6-4:
Monitoring Plan for Receiving Environment

Station Name	Sample Type	Description	Coordinates		Field Parameters	Physical Parameters	General Parameters	BTEX & VH	EPHs & PAHs	Metals[1]	Chronic Toxicity[2]
			Latitude	Longitude							
WQR1[3]	Marine Water	Reference site located northeast of East Creek 500 m northeast of the Project boundary.	49.6694º	-123.2368º	Q (M)	Q (M)	Q (M)	Q (M)	Q (M)	Q (M)	Q
IDZ-E1	Marine Water	IDZ monitoring station at approximately 50 to 100 m southeast of OUT-10.	49.6674	-123.2480	Q (M)	Q (M)	Q (M)	Q (M)	Q (M)	Q (M)	Q
IDZ-E2	Marine Water	IDZ monitoring station at approximately 50 to 100 m southwest of OUT-10.	49.6670	-123.2495	Q (M)	Q (M)	Q (M)	Q (M)	Q (M)	Q (M)	Q

All coordinates are in UTM zone 10 U.
M = monthly
Q = quarterly
Q (M) = monthly for the first year, then quarterly thereafter.
Marine water samples will be collected at 3 depths: 2 m above the seafloor, 2 m below water surface, and 0.5 m below water surface.
[1] Water quality samples will be tested for dissolved and total metals.
[2] Chronic Toxicity testing will be conducted on the marine water sample collected from 0.5 m below the water surface, and will be tested using a fish species and an invertebrate species.
[3] Reference station WQR1 was established in 2021 (Keystone, 2021d and Lorax, 2022b).

6.2.4 Quality Assurance and Quality Control (QA/QC)

A QA/QC program will be implemented to verify the integrity of the collected monitoring data. Quality control samples (*e.g.*, field duplicate, field blank and trip blank) will be collected to assess data quality and can be used to estimate sampling error and variance. The field QA/QC program will be conducted in accordance with the B.C. Field Sampling Manual – Part A: Quality Control and Quality Assurance (Clark, 2013). Laboratory testing will follow the laboratory QA/QC protocols described in the B.C. Environmental Laboratory Manual – Section A Laboratory Quality Assurance / Quality Control (ENV, 2023).

6.2.5 Turbidity-TSS Relationship

A site-specific turbidity-TSS relationship will be established using field measurements paired with laboratory TSS analyses. This relationship will enable personnel to estimate TSS in real time from on-site turbidity measurements for field level evaluation of water quality. The initial relationship will be developed from the construction contact water dataset and will be updated with operations data as they are obtained.

Once the operations contact water turbidity-TSS relationship is established, ongoing compliance with the TSS discharge limit will rely primarily on turbidity measurements interpreted through the site-specific turbidity-TSS curves. Laboratory confirmation sampling will continue at reduced frequencies to validate and refine these relationships at OUT-10 and OWTS-OUT.

Additional information regarding the operational aspects of the turbidity-TSS relationship is available in the Stormwater Drainage Management Plan (Appendix 4.1-1).

7. Closure

7 Closure

This report has been prepared for the exclusive use of WLNG and has been prepared solely for the purpose of supporting an application for a WDA pursuant to the B.C. *Environmental Management Act* for commissioning and operations of the Project. Apart from review and use by the BCER in connection with the above-noted application, the report should not be relied upon by any other party or for any other purpose. Any unauthorized use or reliance on this report by other parties, and any decisions made based on it, are the responsibility of such parties. Lorax accepts no responsibility for any damages that may be suffered by other parties as a result of decisions made or actions based on this report.

Lorax has relied in good faith on information provided by WLNG and its consultants has prepared this technical assessment report in accordance with the level of care and diligence normally exercised by professionals working in environmental science, practicing under similar circumstances in the area, and at the time of the performance of the work. Lorax assumes no responsibility for the completeness or accuracy of the information provided, or for any deficiency in the technical assessment that may have resulted from any inaccuracy or omission in this information. No other warranty is expressed or implied.

Qualified professional declarations of competency and conflict of interest forms are provided in Appendix 7.1-1.

Yours sincerely,

Appendix 1.1: Information Requirements

1.1-1: Information Requirements Table of Concordance

Item No.	Information	Requirements	Location in Final Application
1	**1 PROJECT DESCRIPTION**		
1.1	1.1 Describe the project including proposed facilities, products, processes and discharges. Indicate the maximum intended operating duration (*i.e* ., hours per day, days or months per year).	Required ☑	Section 2.1
1.2	1.2 Provide a detailed map of the project location including facilities and discharges. Identify surrounding land and water uses, and potential environmental receptors.	Required ☑	Figure 1-1, Figure 2-1, Figure 4-4, Figure 4-5
1.3	1.3 Describe the project permitting history and list related reports.	Required ☑	Section 1.2
1.4	1.4 Describe major activities, infrastructure and waste management related to:	Required ☑	Section 2
1.4.1	1.4.1 Site preparation and construction	Required ☑	Section 3.2 and Section 3.3.2
1.4.2	1.4.2 Operations	Required ☑	Section 2.1
1.4.3	1.4.3 Closure and post-closure	Required ☑	Section 2.3
1.5	1.5 Describe specific before and after conditions for permit amendment applications.	Required ☐	Not applicable (this is not an amendment to the existing Construction-phase WDA).
1.6	1.6 List of Qualified Professionals and signed Conflict of Interest & Declaration of Competency.	Required ☑	Appendix 7-1
2	**2 ENVIRONMENTAL SETTINGS:** This section provides information regarding the environmental setting before proposed activities occur. Please follow the British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-Emission, Water, Wastewater, Soil, Sediment, and Biological Samples, BC Ministry of Water, Land and Air Protection, 2013 (or the most recent version) when designing and completing these environmental setting assessments. If environmental settings data collection design and methods differ from the manual, please provide a rationale and discuss with ENV staff at the pre-application stage.		
2.1	2.1 Meteorology and Climate		
2.1.1	2.1.1 Provide a **baseline meteorology and climate assessment** of the project area. The assessment should:		Section 3.4 (Summary)
2.1.1.1	2.1.1.1 Provide a detailed map showing the location of all site-specific and regional meteorological stations in relation to project facilities.	Required ☑	Figure 3-4
2.1.1.2	2.1.1.2 Describe relevant meteorological and climate information sources for parameters such as precipitation, temperature and evaporation.	Required ☑	Section 3.4 (Summary) Stantec, 2020. Woodfibre Hydrometeorology Baseline Report (to be provided upon request).
2.1.1.3	2.1.1.3 Submit all climate data in an appendix (electronic preferred) including site photos, precipitation, temperature, snow water equivalent, *etc* . and provide monthly and annual summaries of relevant climatic parameters.	Required ☑	Section 3.4 Electronic climate data available upon request.
2.1.1.4	2.1.1.4 Identify information gaps and describe site-specific meteorological data collection methods proposed to augment existing regional data.	Required ☑	Section 3.4
2.2	2.2 Surface Water Hydrology		
2.2.1	2.2.1 Provide a **baseline hydrological assessment** of key surface drainages near the project area, to define seasonal flow regimes of local drainages. The assessment should:		Section 3.5 (Summary)
2.2.1.1	2.2.1.1 Provide monthly and annual stream flow/runoff summaries and critical low flow metrics.	Required ☑	Section 3.5.3 and 3.5.4
2.2.1.2	2.2.1.2 Describe the baseline assessment design, methods of hydrometric station installation, monitoring methods and quality control procedures, which should follow guidance in the Resource and Inventory Standards Committee (RISC) Manual of British Columbia Hydrometric Standards (most recent version).	Required ☑	Section 3.5.2 Stantec, 2020 to be provided upon request.
2.2.1.3	2.2.1.3 Provide detailed hydrologic analysis of key surface drainages within the project area to define seasonal flow regimes of local drainages. Include monthly and annual stream flow/runoff summaries and critical low flow metrics.	Required ☑	Section 3.5 Stantec, 2020 to be provided upon request.
2.2.1.4	2.2.1.4 Provide maps showing all drainage basins (local and regional) that will be affected by the proposed project, areas of groundwater discharge, wetlands and notable topographic features.	Required ☑	Figure 3-1, Figure 4-3
2.2.1.5	2.2.1.5 Provide hydrological data in an appendix (electronic preferred), including rating curves, manual measurements, plots of site-specific discharge, site photos, etc.	Required ☑	Stantec, 2020 to be provided upon request.
2.2.1.6	2.2.1.6 Describe spatial or temporal gaps in the database, and provide record periods for all gauging stations (regional and project specific).	Required ☑	Section 3.5.2, 3.5.3 and 3.5.4
2.3	2.3 Hydrogeology		
2.3.1	2.3.1 Provide a **baseline hydrogeological assessment** of the groundwater system around the project. The assessment should:		Section 3.7 (Summary)
2.3.1.1	2.3.1.1 Summarize groundwater information from the provincial databases related to aquifers, and their geology, demand and vulnerability.	Required ☑	Stantec, 2022a. Hydrogeochemical Assessment in Support of Effluent Discharge Permitting (EDP), Rev. G (to be provided upon request).
2.3.1.2	2.3.1.2 Describe the baseline groundwater assessment design, monitoring, analysis and quality control procedures. The baseline assessment must be sufficiently robust to assist with future monitoring and detect potential groundwater changes as a result of the project.	Required ☑	Section 3.7
2.3.1.3	2.3.1.3 Describe aquifers and aquitards below and downgradient of the project, including gradients, storativity, hydraulic conductivity and groundwater flux.	Required ☑	Section 3.7
2.3.1.4	2.3.1.4 Provide a map with groundwater monitoring locations, seepage areas, proposed or existing discharges to ground.	Required ☑	Figure 3-14
2.3.1.5	2.3.1.5 Submit a minimum of one year of groundwater levels and water quality data collected at a quarterly frequency.	Required ☑	Table 3-24 Stantec, 2022a to be provided upon request.
2.3.1.6	2.3.1.6 Describe the monitoring schedule and parameters, monitoring methods and data analysis, including quality controls.	Required ☑	Section 3.7
2.3.1.7	2.3.1.7 Submit water level contour maps, with seasonal variations, depicting groundwater flow direction (both horizontal and vertical, as may be applicable).	Required ☑	Stantec, 2022a to be provided upon request.
2.3.1.8	2.3.1.8 Provide well logs, hydraulic test results, drill core and test pit pictures, monitoring well installation details and hydrostratigraphic cross sections.	Required ☑	Stantec, 2022a to be provided upon request.
2.3.1.9	2.3.1.9 Describe all downgradient groundwater users (e.g. aquatic life, drinking water, etc.) within one kilometer of the project.	Required ☑	Section 3.7

Item No.	Information	Requirements	Location in Final Application
2.3.1.10	2.3.1.10 Describe surface water groundwater interactions downgradient of the project.	Required ☑	Section 3.7
2.3.1.11	2.3.1.11 Develop a conceptual hydrogeological model that synthesizes all relevant information to describe the source-transport-receptor linkages associated with the project.	Required ☑	Not applicable - no discharge to ground.
2.3.1.12	2.3.1.12 For discharges to ground, the groundwater baseline should include assessment of local hydrogeological conditions including, but not limited to, stratigraphy, soil classification, water table elevations, fluctuation and flow direction, soil and aquifer hydraulics including field-saturated hydraulic conductivity, groundwater flux, and subsurface travel times in both unsaturated and saturated zones.	Required ☐	Not applicable - no discharge to ground.
2.4	2.4 Surface Water Quality		
2.4.1	2.4.1 Provide a **baseline surface water quality assessment** for the project. The assessment should include:		Section 3.6 (Summary)
2.4.1.1	2.4.1.1 Identify potential downstream receptor groups (including applicable aquatic life, wildlife, livestock, irrigation, humans) for surface water in relation to proposed project related activities and discharges.	Required ☑	Section 3.11 and Section 5.1
2.4.1.2	2.4.1.2 Describe and justify baseline study design, methods, sampling sites and periods, analysed parameters and QA/QC procedures.	Required ☑	Section 3.6
2.4.1.3	2.4.1.3 Provide a detailed figure with sampling locations in relation to proposed or existing discharge locations, areas of disturbance and distribution of receptors.	Required ☑	Figure 3-13
2.4.1.4	2.4.1.4 Provide data summaries (using appropriate statistics) that characterize spatial and temporal variations and identify location, frequency, seasonality, duration and magnitude of applicable standards exceedances or environmental quality guideline exceedances.	Required ☑	Section 3.6.3
2.4.1.5	2.4.1.5 Provide all raw data in a tabulated form, including applicable method detection limits (in appendices – and Excel compatible electronic files).	Required ☑	Appendix 3.6-1 Electronic files to be provided upon request.
2.4.1.6	2.4.1.6 Identify certified laboratories that conducted sample analysis.	Required ☑	Section 3.6.1
2.4.1.7	2.4.1.7 Identify and discuss QA/QC concerns related to the data.	Required ☑	Section 3.6.2
2.4.1.8	2.4.1.8 Identify and assess spatial or temporal data gaps and uncertainties.	Required ☑	Section 3.6
2.4.1.9	2.4.1.9 For lakes, provide limnological characterizations at a representative deep station for each basin. Sampling design should be adequate to support determination of trophic status.	Required ☐	Not applicable - no lakes at project site.
2.4.1.10	2.4.1.10 Demonstrate that the baseline aquatic life monitoring program is sufficiently robust to assist future monitoring in detecting a significant predetermined change.	Required ☑	Section 3.6
2.5	2.5 Sediment Quality		
2.5.1	2.5.1 Provide a **baseline sediment quality assessment** near the project. The assessment should:		
2.5.1.1	2.5.1.1 Identify potential downstream receptor groups (including applicable aquatic life, wildlife, livestock, irrigation, humans) for sediment in relation to proposed project related activities and discharges.	Required ☑	Section 3.8 (Summary)
2.5.1.2	2.5.1.2 Describe and justify baseline study design, methods, sampling sites and periods, analysed parameters and QA/QC procedures.	Required ☑	Section 3.8
2.5.1.3	2.5.1.3 Provide a detailed figure with sampling locations in relation to proposed or existing discharge locations, areas of disturbance and distribution of receptors.	Required ☑	Figure 3-15
2.5.1.4	2.5.1.4 Provide data summaries (using appropriate statistics) that characterize spatial and temporal variations and identify location, frequency, seasonality, duration and magnitude of applicable standards exceedances or environmental quality guideline exceedances.	Required ☑	Section 3.8.2
2.5.1.5	2.5.1.5 Provide all raw data in a tabulated form, including applicable method detection limits (in appendices – and Excel compatible electronic files).	Required ☑	Appendix 3.8-1 Electronic file to be provided upon request.
2.5.1.6	2.5.1.6 Identify certified laboratories that conducted sample analysis.	Required ☑	Section 3.8.1
2.5.1.7	2.5.1.7 Identify and discuss QA/QC concerns related to the data.	Required ☑	Section 3.8.2
2.5.1.8	2.5.1.8 Identify and assess spatial or temporal data gaps and uncertainties.	Required ☑	Section 3.8
2.5.1.9	2.5.1.9 Demonstrate that the baseline monitoring program is sufficiently robust to assist future monitoring in detecting a significant predetermined change.	Required ☑	Section 3.8
2.6	2.6 Aquatic Life		
2.6.1	2.6.1 Provide a **baseline aquatic life assessment** near the project. The assessment should:		
2.6.1.1	2.6.1.1 Describe and justify baseline study design, methods, sampling sites and periods, analysed parameters and QA/QC procedures.	Required ☑	Section 3.9 and 3.11
2.6.1.2	2.6.1.2 Provide a detailed figure with sampling locations in relation to proposed or existing discharge locations, areas of disturbance and distribution of receptors.	Required ☑	Figure 3-13 and Figure 3-15
2.6.1.3	2.6.1.3 Provide data summaries (using appropriate statistics) that characterize spatial and temporal variations and identify location, frequency, seasonality, duration and magnitude of applicable standards exceedances or environmental quality guideline exceedances.	Required ☑	Section 3.9.3
2.6.1.4	2.6.1.4 Provide all raw data in a tabulated form, including applicable method detection limits (in appendices – and Excel compatible electronic files).	Required ☑	Appendix 3.9-1 Electronic files to be provided upon request.
2.6.1.5	2.6.1.5 Identify certified laboratories that conducted sample analysis.	Required ☑	Section 3.9.1
2.6.1.6	2.6.1.6 Identify and discuss QA/QC concerns related to the data.	Required ☑	Section 3.9.2
2.6.1.7	2.6.1.7 Identify and assess spatial or temporal data gaps and uncertainties.	Required ☑	Section 3.9
2.6.1.8	2.6.1.8 Demonstrate that the baseline aquatic life monitoring program is sufficiently robust to assist future monitoring in detecting a biologically significant predetermined change.	Required ☑	Section 3.9 and Section 3.11

Item No.	Information	Requirements	Location in Final Application
2.7	2.7 Oceanography		
2.7.1.1	2.7.1 Provide **a baseline oceanographic assessment** of key factors that may influence mixing and dispersion of the discharge in the marine or estuarine environment. The analysis must:	Required ☑	Section 3.10 and Figure 3-15
2.7.1.2	2.7.1.2 Identify estuaries and inflows and delineation of their zone of influence.	Required ☑	Section 3.1 and Section 3.10
2.7.1.3	2.7.1.3 Submit maps and analysis of bathymetric features.	Required ☑	Section 3.10 and Figure 3-15
2.7.1.4	2.7.1.4 Identify normal wind direction, tidal influences and marine/stream currents.	Required ☑	Section 3.4.3 and Section 3.10
2.7.1.5	2.7.1.5 Submit inventory receiving water uses including recreational uses, fisheries resources, shellfish areas, water intakes and foreshore uses.	Required ☑	Section 3.11 and Section 5
2.7.1.6	2.7.1.6 Provide drogue studies at proposed outfall terminus location(s) to determine the influence of thermal or physical/chemical stratification characteristics, normal currents over a complete tidal cycle and whether currents are directed shoreward or toward important fisheries or recreational resources.	Required ☑	Section 3.10 Golder, 2015. Metocean Data Analysis Study (to be provided upon request)
2.7.1.7	2.7.1.7 Complete and submit one month of current meter readings (at bottom, and at stratification level).	Required ☑	Golder, 2015 to be provided upon request.
2.7.1.8	2.7.1.8 Complete and submit conductivity/temperature/depth (CTD) profiles during most critical periods to establish stratification levels.	Required ☑	Section 3.10 Golder, 2015 (to be provided upon request).
2.7.1.9	2.7.1.9 Identify and assess spatial and temporal data gaps and uncertainties.	Required ☑	Section 3.10
3	**3 EFFLUENT DISCHARGES, MITIGATION, MANAGEMENT AND/OR TREATMENT**		
3.1	3.1 Provide a process flow diagram showing the waste streams.	Required ☑	Figure 4-1 and Figure 4-2
3.2	3.2 Provide full characterization of all effluent sources from the site. Indicate their source, maximum and average quality,quantity and frequency. Describe the methodology used for characterization.	Required ☑	Section 4.1
3.3	3.3 Provide a detailed site plan that includes locations and coordinates for each discharge location (coordinates must be in decimal degrees to the fourth decimal place).	Required ☑	Figure 2-1, Figure 4-4, Figure 4-5, Figure 6-1, Section 6.1.2
3.4	3.4 Describe mitigation measures to be used to limit discharge rates and contaminant concentrations.	Required ☑	Section 4.1 and 4.2
3.5	3.5 If untreated effluent concentrations at the source are predicted to exceed acute BC Water Quality Gudelines (BCWQG) undertake and submit a Best Achievable Technology Review by a Qualified Professional (QP) (see current *Fact Sheet Waste Discharges – Best Achievable Technology*). Note: Where needed, an Initial Dilution Zone (IDZ) may typically only be considered after implementation of BAT.	Required ☑	Section 4.2.1 and Appendix 4.2-1
3.6	3.6 If treatment is proposed, provide the following information:		
3.6.1	3.6.1 Specify the treatment design criteria including treatment capacity, retention times, and input and output water quantity and quality.	Required ☑	Section 4.2.1.2 and 4.2.2
3.6.2	3.6.2 Provide treatment system detailed design drawings including discharge works, certified, signed and stamped by a qualified professional.	Required ☑	Appendix 4.1-3 and Appendix 4.2-3
3.6.3	3.6.3 Provide rationale for expected treatment effectiveness (*e.g.,* examples with similar conditions, bench scale tests, pilot tests), including an evaluation of effectiveness under potential variable operating conditions (*e.g* ., flood or storm events).	Required ☑	Section 4.2.3
3.6.4	3.6.4 Describe all treatment process by-products (liquid, solid and gaseous), including quantity and quality, and provide a management plan for each, including sludge management plan if applicable.	Required ☑	Section 4.2.2.4 and Appendix 4.1-1
3.7	3.7 Propose effluent discharge limits for contaminants of potential concern that can be shown to be protective of the receiving environment and its receptors.	Required ☑	Section 6.2
3.8	3.8 Describe the proposed sampling and flow measuring facilities at discharge points.	Required ☑	Section 6.1
3.9	3.9 Describe the storm water management system and provide detailed design for proposed storm water works.	Required ☑	Section 4.1.5 and Appendix 4.1-3
3.10	3.10 Certification by Qualified Professionals - QP sign-off certifying that the wastewater facility as designed and/or as-constructed is capable of meeting the proposed discharge requirements.	Required ☑	Appendix 4.2-4
3.11	3.11 Provide project and treatment system construction and commissioning schedule and related notification requirements.	Required ☑	Section 2.2 and Section 4.1.10
3.12	3.12 Provide a detailed description of any use of reclaimed water (effluent), including: o A detailed description of the intended use. o Planned or potential public and/or worker exposure. o An evaluation of the implications for effluent quality based on potential exposure and user safety.	Required ☐	Not applicable - reclaimed water use is not planned.
4	**4 ENVIRONMENTAL EFFECTS PREDICTION AND IMPACT ASSESSMENT**		
4.1	4.1 Identify the receptors and/or environmental values that may be at risk due to project related activities.	Required ☑	Section 5.1 and Section 5.4
4.2	4.2 Provide a figure, identify and justify spatial and temporal boundaries for effects predictions.	Required ☑	Section 4.4, Section 5 and Figure 6-1
4.3	4.3 Develop and submit a Conceptual Site Model. Describe and illustrate graphically the contaminant source, transport pathways from source to receptors. Estimate probabilities of occurrence and the risk, and develop a risk management matrix.	Required ☑	Section 4.3.1, Figure 4-12 Section 5, Figure 5-1
4.4	4.4 Describe the size and edge of the Initial Dilution Zone (IDZ) at which point the BCWQG must be met. Please refer to the ENV Interim Technical Guidance 11: Development and Use of Initial Dilution Zones in Effluent Discharge Authorizations.	Required ☑	Section 4.4 and Section 6.1
4.5	4.5 Identify by location and receptor groups, potential for effects as well as frequency, seasonality, magnitude and reversibility of the effects. Provide rationale for the effects assessment. Demonstrate through a weight of evidence approach that effluent and non-point source discharges will not cause toxicity within the IDZ (acute) and outside of the IDZ (acute or chronic). Identify any residual effects.	Required ☑	Section 5

Item No.	Information	Requirements	Location in Final Application
4.6	4.6 Provide predicted incremental changes (*e.g* . monthly/annually) over existing receiving environment water, sediment quality and/or tissue quality at critical points downstream (*e.g.* within IDZ, edge of IDZ, near field and far field, sensitive habitat) and during critical time periods (*e.g.* low dilution 7Q10, high flows, spawning, hatching, *etc.*) This should be included for all project phases.	Required ☑	Section 4.3 and Section 4.4
4.7	4.7 Identify all locations, parameters, time periods, magnitude, frequency and seasonality for which exceedances of BCWQGs, Sediment Quality Guidelines, tissue guidelines, or applicable standards are predicted to occur in water, sediment or tissue quality.	Required ☑	Section 4.3 and Section 5
4.8	4.8 Describe predicted effects of project related activities, including all effluent and non-point discharges on the water balance, flows and water levels.	Required ☑	Section 4.3, Section 4.4 and Section 5
4.9	4.9 Explain and justify assessment (*e.g* ., drinking water quality, recreation, aquatic life, wildlife, livestock, irrigation) and measurement endpoints (chemical, toxicological or biological) to identify expected and realistic worst case seasonal effects and trends.	Required ☑	Section 4.3
4.10	4.10 Describe and discuss the potential for bioaccumulation or bioconcentration of contaminants, and the associated risk to assessment endpoints (*i.e.* , fish health, fish reproduction, consumers of fish, *etc.*).	Required ☑	Section 5
4.11	4.11 Predict changes in aquatic receptors at species, community and/or ecosystem levels as appropriate due to water quality and water quantity changes due to the project, other anthropogenic activities and considering climate change.	Required ☑	Section 5
4.12	4.12 Identify risks to non-aquatic receptors, including wildlife, livestock and human health.	Required ☑	Section 5.1
4.13	4.13 Validate proposed effluent quality requirements based on a thorough assessment of discharge loading, and the effects assessment.	Required ☑	Section 4.3 and Section 5
4.14	4.14 Identify data gaps, uncertainties and risk and describe how they will be reduced and/or addressed in adaptive management and environmental monitoring programs.	Required ☑	Section 4.1 and Appendix 4.1-1
4.15	4.15 Where **models** are used:		
4.15.1	4.15.1 Conduct sensitivity analysis for the **water quality** model to identify the input parameters of most consequence to the model output. Consider the widest reasonable range of model inputs including but not limited to: o hydro-climatic - wet and dry events representative of the streamflow variability in the project area o hydrogeologic – groundwater recharge, water levels and hydraulic conductivity o water quality - address uncertainty with regards to attenuation, water treatment, source terms, etc.	Required ☑	Section 4.3
4.15.2	4.15.2 Describe and justify receiving environment modelling approaches. Describe the models type, its assumptions, inputs and outputs.	Required ☑	Section 4.3
4.15.3	4.15.3 Provide calibration/validation statistics and plots for the models used.	Required ☑	Section 4.3
4.15.4	4.15.4 Identify data gaps, assumptions and uncertainty in the models used, and how they will be addressed.	Required ☑	Section 4.3
4.16	4.16 For impact assessment related to discharge to ground provide:		Not applicable - no discharge to ground.
4.16.1	4.16.1 Summary of the baseline hydrogeological setting and downgradient groundwater users (e.g. aquatic life, drinking water).	Required ☐	Not applicable - no discharge to ground.
4.16.2	4.16.2 Description of the infiltration system, including its design and operation, maintenance and equipment monitoring.	Required ☐	Not applicable - no discharge to ground.
4.16.3	4.16.3 Description of the effluent treatment method, quantity and quality.	Required ☐	Not applicable - no discharge to ground.
4.16.4	4.16.4 Description of the 3-dimensional size of the IDZ zone, including its edge where the groundwater standards must be met. Describe the location of the edge of the IDZ in relation to the property boundary, the nearest water supply well or surface water.	Required ☐	Not applicable - no discharge to ground.
4.16.5	4.16.5 Estimation of the size of the groundwater mound from the proposed discharge and whether the mound or the discharge may extent to or daylight at ground surface.	Required ☐	Not applicable - no discharge to ground.
4.17	4.17 Methods and outcomes to predict effects from the proposed discharge on groundwater, including results and assumptions of modelling efforts (e.g. water balance, mass balance, numerical flow, contaminant transport).	Required ☐	Not applicable - no discharge to ground.
4.18	4.18 Identify data gaps, assumptions and uncertainty in the models, and how they will be addressed.	Required ☐	Not applicable - no discharge to ground.
5	**5 DISCHARGE AND ENVIRONMENTAL MONITORING PROGRAMS**		
5.1	5.1 For all programs identify the objectives, and describe and justify the proposed study design/plan.	Required ☑	Section 6.1
5.2	5.2 Discharge Monitoring Program – describe how you will monitor the effluent discharge including location, frequency, parameters, QA/QC measures, and comparison to proposed discharge limits.	Required ☑	Section 6.1
5.3	5.3 Receiving environment monitoring programs - describe the pathway and receptor linkages:		
5.3.1	5.3.1 Groundwater Monitoring Program - include the number of monitoring wells to measure the background and receiving groundwater levels and quality, and maps depicting the monitoring sites. The program should summarize the monitoring well installation details, such as geographical coordinates of all wells, installation depth, screen interval and geology, and water levels. The plan should detail the sampling methods, monitoring parameters, frequency, and the applicable BC Contaminated Sites Regulation standards that will be met at the edge of the initial dilution zone.	Required ☐	Not applicable - no discharge to ground.
5.3.2	5.3.2 Surface Water Monitoring Program - include a plan to validate model predictions, where applicable the program may also include IDZ monitoring. The program should be developed to detect change and impacts.	Required ☐	Not applicable - no treated water will be discharged to freshwater.
5.3.3	5.3.3 Marine Water Monitoring Program - include a plan to validate model predictions, assess water quality guidelines are being met and detect change and impacts to the receiving environment. The program should include at least: one control sampling station located outside the influence of the IDZ, a sampling station at the end of pipe, 3 sampling stations at the IDZ. Samples should be taken at the modelled trapping depth, surface and at depth. Sampling frequency should be 5 weekly samples in 30 days.	Required ☑	Section 6.1
5.3.4	5.3.4 Aquatic / Environmental Effects Monitoring Program – include weight of evidence assessment and cumulative effects monitoring in areas that may potentially be affected by anthropogenic activities. Demonstrate that the monitoring program is sufficiently robust to assist in detecting a biologically significant predetermined change.	Required ☑	Section 5 and Section 6.1
5.4	5.4 Describe and justify proposed data assessment techniques and reporting, including frequency and content, and notification requirements.	Required ☑	Section 6.1
5.5	5.5 Describe and justify quality assurance/quality control procedures.	Required ☑	Section 6.1.4

Item No.	Information	Requirements	Location in Final Application
6	**6 MANAGEMENT PLANS**		
6.1	6.1 Operations and Maintenance Manual – Detailed operational procedures and preventative maintenance program, operator training and qualifications, inspection schedule, inventory of replacement parts, description of automated systems, warnings and alarms, including response and notification procedures.	Required ☑	Section 4.2.5 and Appendix 4.2-6
6.2	6.2 Treatment Residuals Management Plan - Provide a plan for disposing of treatment residuals in a manner approved under the *Environmental Management Act.*	Required ☑	Section 4.2.2.4 and Appendix 4.1-1
6.3	6.3 Commissioning Plan - Contains the notification, operational procedures and monitoring required to commission the facility.	Required ☑	Section 2.2, Section 4.2.6 and Section 4.1.10
6.4	6.4 Contingency Plan - Describes emergency procedures for the facility, stand-by or emergency power requirements, procedures for notifying a health officer when necessary, actions to take if the effluent fails to meet quality requirements, and alternate disposal or storage options (for reclaimed water when use is not possible).	Required ☑	Section 4.1.8 and Appendix 4.1-1
6.5	6.5 Episode Management Plan – Includes spills, nuisance, litter, odour, fire, flooding.	Required ☑	Section 4.1.9 and Appendix 4.1-1
6.6	6.6 Erosion and Sediment Control Plan – Contains planning and actions to mitigate erosion and sediment runoff during the project development and operation.	Required ☑	Table 4-2, Section 4.1.3, Section 4.1.5, and Appendix 4.1-3
6.7	6.7 Trigger and Response Plan – Describes monitoring triggers, responses, including confirmatory monitoring and mitigation strategies and implementation in the event that environmental benchmarks in the receiving environment, such as water guidelines, groundwater standards, and toxicology failures, are exceeded.	Required ☑	Section 4.1.6 and Appendix 4.1-1
6.8	6.8 Adaptive Management Plan – Describes and addresses outstanding key uncertainties of potential effects of the discharge following a cyclical process.	Required ☑	Section 4.1.7 and Appendix 4.1-1
6.9	6.9 Irrigation Plan - Documents the timing of reclaimed water use, maximum application rate and growing season based on the crop or vegetation, site specific loading, and nutrient and metals limits.	Required ☐	Not applicable - irrigation is not planned.
6.10	6.10 Odour Control Plan – Contains planning and actions to mitigate odour generation during the project construction and operation.	Required ☐	Not required - nuisance odours are not expected in relation to the water management systems.
6.11	6.11 Closure Plan - In the case of a temporary treatment system, details decommissioning procedures for the facility.	Required ☐	Not applicable - system is not temporary.
7	**7 SEWAGE DISPOSAL** (Not required if a Municipal Wastewater Regulation (MWR) registration is being pursued or if connected to an authorized system. May ONLY be included in effluent permit if the sewage discharge is combined with subject effluent and is <10% of that combined flow as per section 5(1)(b) of the MWR prior to discharge)		Not applicable - sewage treatment system is a separate permit & separate outfall from the stormwater effluent systems.
7.1	7.1 Describe treatment and disposal plan for sewage generated on-site including the maximum volume.	Required ☐	Not applicable.
7.2	7.2 Provide a copy of the design drawings for the sewage treatment facility, signed and stamped by a qualified professional.	Required ☐	Not applicable.
7.3	7.3 Provide Commissioning, Operating and Contingency Plans as per MWR Part 2: Division 4.	Required ☐	Not applicable.
7.4	7.4 Provide sewage treatment facility classification (or pre-classification) under the Environmental Operators Certification Program (EOCP).	Required ☐	Not applicable.
7.5	7.5 Provide operator qualifications and certification under the Environmental Operators Certification Program (EOCP).	Required ☐	Not applicable.
7.6	7.6 Provide an effluent flow and quality monitoring plan.	Required ☐	Not applicable.

Appendix 3.2: Soil Quality Results

Notes:
Empty cells indicate no result was reported for that parameter.
Values above BC Contaminated Sites Regulations for industrial land use are shaded in grey.
Values beginning with < indicates a detection limit.
Sample class M is a monitoring sample; sample class D is a duplicate sample.

Appendix 3.2-1 Soil Quality Monitoring Results - Upland

Notes:
Empty cells indicate no result was reported for that parameter.
Values above BC Contaminated Sites Regulations for industrial land use are shaded in grey.
Values beginning with < indicates a detection limit.
Sample class M is a monitoring sample; sample class D is a duplicate sample.

Appendix 3.2-1 Soil Quality Monitoring Results - Upland

Table 1: Soil Quality Monitoring Results

Station ID	Lab ID	Sample Date/Time	Sample Class	Dibenz(a-h)anthracene	Fluoranthene	Fluorene	Indeno(1,2,3-cd)pyrene	1-Methylnaphthalene	2-Methylnaphthalene	Naphthalene	Phenanthrene	Pyrene	Quinoline	Aluminum (Al)	Antimony (Sb)	Arsenic (As)	Barium (Ba)	Beryllium (Be)
				mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg	mg/kg

Notes:
Empty cells indicate no result was reported for that parameter.
Values above BC Contaminated Sites Regulations for industrial land use are shaded in grey.
Values beginning with < indicates a detection limit.
Sample class M is a monitoring sample; sample class D is a duplicate sample.

Appendix 3.2-1 Soil Quality Monitoring Results - Upland

Notes:
Empty cells indicate no result was reported for that parameter.
Values above BC Contaminated Sites Regulations for industrial land use are shaded in grey.
Values beginning with < indicates a detection limit.
Sample class M is a monitoring sample; sample class D is a duplicate sample.

Appendix 3.2-1 Soil Quality Monitoring Results - Upland

Empty cells indicate no result was reported for that parameter.
1: Relative Percent Difference is calculated only if one or both values are greater than 5x the detection limit
2: RPDs exceeding 20% are flagged in light grey
3: RPDs exceeding 50% are flagged in dark grey

Notes:
Empty cells indicate no result was reported for that parameter.
Values above BC Contaminated Sites Regulations for industrial land use are shaded in grey.
Values beginning with < indicates a detection limit.
Sample class M is a monitoring sample; sample class D is a duplicate sample.

Notes:
EC = Electrical Conductivity
IC = Ion Chromatography
mg/L = Milligrams per Litre
n/v = no value
RDL= reported detection limit
Federal WQG = Federal, Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) Marine Aquatic Life Guideline
BC WQG = British Columbia Marine Aquatic Life Guideline
Values in red font are above the long-term BC WQG
Values shaded in grey are above the short-term BC WQG
Values italicized and underlined are above the Federal WQG

Notes:
EC = Electrical Conductivity
IC = Ion Chromatography
mg/L = Milligrams per Litre
n/v = no value
RDL= reported detection limit
Federal WQG = Federal, Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) Marine Aquatic Life Guideline
BC WQG = British Columbia Marine Aquatic Life Guideline
Values in red font are above the long-term BC WQG
Values shaded in grey are above the short-term BC WQG
Values italicized and underlined are above the Federal WQG

Notes:
EC = Electrical Conductivity
IC = Ion Chromatography
mg/L = Milligrams per Litre
n/v = no value
RDL= reported detection limit
Federal WQG = Federal, Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) Marine Aquatic Life Guideline
BC WQG = British Columbia Marine Aquatic Life Guideline
Values in red font are above the long-term BC WQG
Values shaded in grey are above the short-term BC WQG
Values italicized and underlined are above the Federal WQG

Notes:
Sample Class 'M' = monitoring, 'F' = field measurements only.
Values with '<' preceeding the result are below the analytical detection limit.

Notes:
Sample Class 'M' = monitoring, 'F' = field measurements only.
Values with '<' preceeding the result are below the analytical detection limit.
